1.   Introduction.   This is HiTeX, a program derived from TeX, extending its capabilities using ε-TeX and PROTE, and adding functions common to other engines from the TeX Live distribution. HiTeX writes output files in the HINT file format. Like TeX, it is a document compiler intended to produce typesetting of high quality. The Pascal program that follows is the definition of TeX82, a standard version of TeX that is designed to be highly portable so that identical output will be obtainable on a great variety of computers.

A main purpose of the following program is to explain the algorithms of TeX as clearly as possible. As a result, the program will not necessarily be very efficient when a particular Pascal compiler has translated it into a particular machine language. However, the program has been written so that it can be tuned to run efficiently in a wide variety of operating environments by making comparatively few changes. Such flexibility is possible because the documentation that follows is written in the WEB language, which is at a higher level than Pascal; the preprocessing step that converts WEB to Pascal is able to introduce most of the necessary refinements. Semi-automatic translation to other languages is also feasible, because the program below does not make extensive use of features that are peculiar to Pascal.

A large piece of software like TeX has inherent complexity that cannot be reduced below a certain level of difficulty, although each individual part is fairly simple by itself. The WEB language is intended to make the algorithms as readable as possible, by reflecting the way the individual program pieces fit together and by providing the cross-references that connect different parts. Detailed comments about what is going on, and about why things were done in certain ways, have been liberally sprinkled throughout the program. These comments explain features of the implementation, but they rarely attempt to explain the TeX language itself, since the reader is supposed to be familiar with *The TeXbook*.

2.   The present implementation has a long ancestry, beginning in the summer of 1977, when Michael F. Plass and Frank M. Liang designed and coded a prototype based on some specifications that the author (in the following, unless specified, "the author" refers to D.E. Knuth) had made in May of that year. This original protoTeX included macro definitions and elementary manipulations on boxes and glue, but it did not have line-breaking, page-breaking, mathematical formulas, alignment routines, error recovery, or the present semantic nest; furthermore, it used character lists instead of token lists, so that a control sequence like \halign was represented by a list of seven characters. A complete version of TeX was designed and coded by the author in late 1977 and early 1978; that program, like its prototype, was written in the SAIL language, for which an excellent debugging system was available. Preliminary plans to convert the SAIL code into a form somewhat like the present "web" were developed by Luis Trabb Pardo and the author at the beginning of 1979, and a complete implementation was created by Ignacio A. Zabala in 1979 and 1980. The TeX82 program, which was written by the author during the latter part of 1981 and the early part of 1982, also incorporates ideas from the 1979 implementation of TeX in MESA that was written by Leonidas Guibas, Robert Sedgewick, and Douglas Wyatt at the Xerox Palo Alto Research Center. Several hundred refinements were introduced into TeX82 based on the experiences gained with the original implementations, so that essentially every part of the system has been substantially improved. After the appearance of "Version 0" in September 1982, this program benefited greatly from the comments of many other people, notably David R. Fuchs and Howard W. Trickey. A final revision in September 1989 extended the input character set to eight-bit codes and introduced the ability to hyphenate words from different languages, based on some ideas of Michael J. Ferguson.

No doubt there still is plenty of room for improvement, but the author is firmly committed to keeping TeX82 "frozen" from now on; stability and reliability are to be its main virtues.

On the other hand, the WEB description can be extended without changing the core of TeX82 itself, and the program has been designed so that such extensions are not extremely difficult to make. The *banner* string defined here should be changed whenever TeX undergoes any modifications, so that it will be clear which version of TeX might be the guilty party when a problem arises.

This program contains code for various features extending TeX, therefore this program is called 'PRoTE' and not 'TeX'; the official name 'TeX' by itself is reserved for software systems that are fully compatible with each other. A special test suite called the "TRIP test" is available for helping to determine whether a particular implementation deserves to be known as 'TeX' [cf. Stanford Computer Science report CS1027, November 1984].

A similar test suite called the "SELLETTE test" is available for helping to determine whether a particular implementation deserves to be known as 'PRoTE'.

#**define** *eTeX_version* 2   ▷ \eTeXversion ◁
#**define** *eTeX_revision* ".6"   ▷ \eTeXrevision ◁
#**define** *eTeX_version_string* "-2.6"   ▷ current ε-TeX version ◁

      eTeX_version_string"-"HINT_VERSION_STRING"␣"TL_VERSION   ▷ printed when TeX starts ◁

3.   Different Pascals have slightly different conventions, and the present program expresses TeX in terms of the Pascal that was available to the author in 1982. Constructions that apply to this particular compiler, which we shall call Pascal-H, should help the reader see how to make an appropriate interface for other systems if necessary. (Pascal-H is Charles Hedrick's modification of a compiler for the DECsystem-10 that was originally developed at the University of Hamburg; cf. *Software—Practice and Experience* **6** (1976), 29–42. The TeX program below is intended to be adaptable, without extensive changes, to most other versions of Pascal, so it does not fully use the admirable features of Pascal-H. Indeed, a conscious effort has been made here to avoid using several idiosyncratic features of standard Pascal itself, so that most of the code can be translated mechanically into other high-level languages. For example, the '**with**' and '*new*' features are not used, nor are pointer types, set types, or enumerated scalar types; there are no '**var**' parameters, except in the case of files — ε-TeX, however, does use '**var**' parameters for the *reverse* function; there are no tag fields on variant records; there are no assignments $\textbf{double} \leftarrow \textbf{int}$; no procedures are declared local to other procedures.)

The portions of this program that involve system-dependent code, where changes might be necessary because of differences between Pascal compilers and/or differences between operating systems, can be identified by looking at the sections whose numbers are listed under 'system dependencies' in the index. Furthermore, the index entries for 'dirty Pascal' list all places where the restrictions of Pascal have not been followed perfectly, for one reason or another.

Incidentally, Pascal's standard *round* function can be problematical, because it disagrees with the IEEE floating-point standard. Many implementors have therefore chosen to substitute their own home-grown rounding procedure.

4.   The following is an outline of the program, whose components will be filled in later, using the conventions of `cweb`. For example, the portion of the program called '⟨ Global variables 13 ⟩' below will be replaced by a sequence of variable declarations that starts in §13 of this documentation. In this way, we are able to define each individual global variable when we are prepared to understand what it means; we do not have to define all of the globals at once. Cross references in §13, where it says "See also sections 20, 26, . . . ," also make it possible to look at the set of all global variables, if desired. Similar remarks apply to the other portions of the program.

The program starts with inserting header files and occassionaly a function must be placed before declaring TeX's macros, because the function uses identifiers that TeX will declare as macros.

⟨ Header files and function declarations 9 ⟩
⟨ Preprocessor definitions ⟩

enum { ⟨ Constants in the outer block 11 ⟩ };

⟨ Types in the outer block 18 ⟩
⟨ Forward declarations 52 ⟩
⟨ Global variables 13 ⟩

static void *initialize*(**void**)   ▷ this procedure gets things started properly ◁
{ ⟨ Local variables for initialization 19 ⟩
  ⟨ Initialize whatever TeX might access 8 ⟩
}
⟨ Basic printing procedures 56 ⟩
⟨ Error handling procedures 72 ⟩

5.   The overall TeX program begins with the heading just shown, after which comes a bunch of procedure declarations and function declarations. Finally we will get to the main program, which begins with the comment '*start_here*'. If you want to skip down to the main program now, you can look up '*start_here*' in the index. But the author suggests that the best way to understand this program is to follow pretty much the order of TeX's components as they appear in the WEB description you are now reading, since the present ordering is intended to combine the advantages of the "bottom up" and "top down" approaches to the problem of understanding a somewhat complicated system.

6.   There is no need to declare labels in C.

7.   Some of the code below is intended to be used only when diagnosing the strange behavior that sometimes occurs when TEX is being installed or when system wizards are fooling around with TEX without quite knowing what they are doing. Such code will not normally be compiled; it is delimited by the codewords '#**ifdef** DEBUG ... #**endif**', with apologies to people who wish to preserve the purity of English.

Similarly, there is some conditional code delimited by '#**ifdef** STAT ... #**endif**' that is intended for use when statistics are to be kept about TEX's memory usage. The #**ifdef** STAT ... #**endif** code also implements diagnostic information for \tracingparagraphs, \tracingpages, and \tracingrestores.

8.   This program has two important variations: (1) There is a long and slow version called INITEX, which does the extra calculations needed to initialize TEX's internal tables; and (2) there is a shorter and faster production version, which cuts the initialization to a bare minimum. Parts of the program that are needed in (1) but not in (2) are delimited by the codewords '#**ifdef** INIT ... #**endif**'.

TEX Live has established the common practice to select the initialization code at runtime using the *iniversion* variable.

⟨ Initialize whatever TEX might access 8 ⟩ ≡
  ⟨ Set initial values of key variables 21 ⟩
#**ifdef** INIT
   if (*iniversion*)   ▷ TEX Live ◁
   { ⟨ Initialize table entries (done by INITEX only) 164 ⟩ }
#**endif**

This code is used in section 4.

9.   The declaration of all basic type definitions needed by HiTEX are contained in a system dependent header file.

⟨ Header files and function declarations 9 ⟩ ≡
#**include** "hibasetypes.h"
#**include** <string.h>
#**include** <math.h>

See also sections 1693, 1844, 1856, 1894, and 1895.

This code is used in section 4.

10.   Further it is necessary to define some build in primitives of Pascal that are otherwise not available in C.

#**define** *odd*(X) ((X) & 1)
#**define** *chr*(X) ((**unsigned char**)(X))
#**define** *ord*(X) ((**unsigned int**)(X))
#**define** *abs*(X) ((X) > −(X) ? (X) : −(X))
#**define** *round*(X) ((**int**)((X) ≥ 0.0 ? *floor*((X) + 0.5) : *ceil*((X) − 0.5)))

11. The following parameters can be changed at compile time to extend or reduce TeX's capacity. They may have different values in `INITEX` and in production versions of TeX.

⟨ Constants in the outer block 11 ⟩ ≡

$mem\_max \leftarrow 5000000,$ ▷ greatest index in TeX's internal mem array; must be strictly less than $max\_halfword$; must be equal to mem_top in `INITEX`, otherwise $\geq mem\_top$ ◁

$mem\_min \leftarrow 0,$ ▷ smallest index in TeX's internal mem array; must be $min\_halfword$ or more; must be equal to mem_bot in `INITEX`, otherwise $\leq mem\_bot$ ◁

$buf\_size \leftarrow 2000000,$ ▷ maximum number of characters simultaneously present in current lines of open files and in control sequences between \csname and \endcsname; must not exceed $max\_halfword$ ◁

$error\_line \leftarrow 79,$ ▷ width of context lines on terminal error messages ◁

$half\_error\_line \leftarrow 50,$

    ▷ width of first lines of contexts in terminal error messages; should be between 30 and $error\_line - 15$ ◁

$max\_print\_line \leftarrow 79,$ ▷ width of longest text lines output; should be at least 60 ◁

$stack\_size \leftarrow 5000,$ ▷ maximum number of simultaneous input sources ◁

$max\_in\_open \leftarrow 15,$

    ▷ maximum number of input files and error insertions that can be going on simultaneously ◁

$font\_max \leftarrow 255,$ ▷ maximum internal font number; must not exceed $max\_quarterword$ and must be at most $font\_base + 256$ ◁

$font\_mem\_size \leftarrow 8000000,$ ▷ number of words of $font\_info$ for all fonts ◁

$param\_size \leftarrow 10000,$ ▷ maximum number of simultaneous macro parameters ◁

$nest\_size \leftarrow 500,$ ▷ maximum number of semantic levels simultaneously active ◁

$max\_strings \leftarrow 500000,$ ▷ maximum number of strings; must not exceed $max\_halfword$ ◁

$string\_vacancies \leftarrow 90000,$ ▷ the minimum number of characters that should be available for the user's control sequences and font names, after TeX's own error messages are stored ◁

$pool\_size \leftarrow 6250000,$ ▷ maximum number of characters in strings, including all error messages and help texts, and the names of all fonts and control sequences; must exceed $string\_vacancies$ by the total length of TeX's own strings, which is currently about 23000 ◁

$save\_size \leftarrow 100000,$ ▷ space for saving values outside of current group; must be at most $max\_halfword$ ◁

$trie\_size \leftarrow 1000000,$

    ▷ space for hyphenation patterns; should be larger for `INITEX` than it is in production versions of TeX ◁

$trie\_op\_size \leftarrow 35111,$ ▷ space for "opcodes" in the hyphenation patterns ◁

$dvi\_buf\_size \leftarrow 16384,$ ▷ size of the output buffer; must be a multiple of 8 ◁

$file\_name\_size \leftarrow 1024,$ ▷ file names shouldn't be longer than this ◁

$xchg\_buffer\_size \leftarrow 64,$ ▷ must be at least 64 ◁

    ▷ size of $eight\_bits$ buffer for exchange with system routines ◁

$empty\_string \leftarrow 256$ ▷ the empty string follows after 256 characters ◁

This code is used in section 4.

12.   Like the preceding parameters, the following quantities can be changed at compile time to extend or reduce TEX's capacity. But if they are changed, it is necessary to rerun the initialization program INITEX to generate new tables for the production TEX program. One can't simply make helter-skelter changes to the following constants, since certain rather complex initialization numbers are computed from them. They are defined here using WEB macros, instead of being put into Pascal's **const** list, in order to emphasize this distinction.

#**define** mem_bot 0
            ▷ smallest index in the mem array dumped by INITEX; must not be less than mem_min ◁
#**define** mem_top 5000000   ▷ largest index in the mem array dumped by INITEX; must be substantially
            larger than mem_bot and not greater than mem_max ◁
#**define** $font\_base$ 0   ▷ smallest internal font number; must not be less than $min\_quarterword$ ◁
#**define** $hash\_size$ 45000   ▷ maximum number of control sequences; it should be at most about
            $(mem\_max - mem\_min)/(\textbf{double})\,10$ ◁
#**define** $hash\_prime$ 35999   ▷ a prime number equal to about 85% of $hash\_size$ ◁
#**define** $hyph\_size$ 8191   ▷ another prime; the number of \hyphenation exceptions ◁

13.   In case somebody has inadvertently made bad settings of the "constants," TEX checks them using a global variable called bad.

This is the first of many sections of TEX where global variables are defined.

⟨ Global variables 13 ⟩ ≡
    static int bad;   ▷ is some "constant" wrong? ◁

See also sections 20, 26, 30, 32, 39, 54, 73, 76, 79, 96, 104, 115, 116, 117, 118, 124, 165, 173, 181, 213, 246, 253, 256, 271, 286, 297, 301, 304, 305, 308, 309, 310, 333, 361, 382, 387, 388, 410, 438, 447, 480, 489, 493, 512, 513, 527, 532, 539, 549, 550, 555, 592, 595, 605, 616, 646, 647, 661, 684, 719, 724, 765, 770, 814, 821, 823, 825, 828, 833, 839, 847, 872, 892, 900, 905, 907, 921, 926, 943, 947, 950, 971, 980, 982, 989, 1032, 1074, 1266, 1281, 1299, 1305, 1331, 1342, 1345, 1384, 1392, 1434, 1457, 1498, 1500, 1519, 1530, 1531, 1539, 1543, 1567, 1582, 1635, 1646, 1647, 1672, 1678, 1846, 1852, 1873, and 1883.

This code is used in section 4.

14.   Later on we will say 'if $(mem\_max \geq max\_halfword)$ $bad \leftarrow 14$', or something similar. (We can't do that until $max\_halfword$ has been defined.)

⟨ Check the "constant" values for consistency 14 ⟩ ≡
    $bad \leftarrow 0$;
    if $((half\_error\_line < 30) \vee (half\_error\_line > error\_line - 15))$ $bad \leftarrow 1$;
    if $(max\_print\_line < 60)$ $bad \leftarrow 2$;
    if $(dvi\_buf\_size \% 8 \neq 0)$ $bad \leftarrow 3$;
    if $(mem\_bot + 1100 > mem\_top)$ $bad \leftarrow 4$;
    if $(hash\_prime > hash\_size)$ $bad \leftarrow 5$;
    if $(max\_in\_open \geq 128)$ $bad \leftarrow 6$;
    if $(mem\_top < 256 + 11)$ $bad \leftarrow 7$;   ▷ we will want $null\_list > 255$ ◁

See also sections 111, 290, and 1249.

This code is used in section 1332.

15.   Labels are given symbolic names by the following definitions, so that occasional **goto** statements will be meaningful. We insert the label 'end' just before the '}' of a procedure in which we have used the '**goto** end' statement defined below; the label '$restart$' is occasionally used at the very beginning of a procedure; and the label '$reswitch$' is occasionally used just prior to a **case** statement in which some cases change the conditions and we wish to branch to the newly applicable case. Loops that are set up with the **loop** construction defined below are commonly exited by going to '$done$' or to '$found$' or to 'not_found', and they are sometimes repeated by going to '$resume$'. If two or more parts of a subroutine start differently but end up the same, the shared code may be gathered together at '$common\_ending$'.

Incidentally, this program never declares a label that isn't actually used, because some fussy Pascal compilers will complain about redundant labels.

16.   Here are some macros for common programming idioms.

#**define** $incr(A)$ $A \leftarrow A + 1$ ▷ increase a variable by unity ◁
#**define** $decr(A)$ $A \leftarrow A - 1$ ▷ decrease a variable by unity ◁
#**define** $negate(A)$ $A \leftarrow -A$ ▷ change the sign of a variable ◁
#**define** **loop**   **while** $(true)$ ▷ repeat over and over until a **goto** happens ◁
   format $loop$ $else$ ▷ WEB's **loop** acts like 'while $true$ **do**' ◁
#**define** $do\_nothing$ ▷ empty statement ◁
#**define** $empty$ 0   ▷ symbolic name for a null constant ◁

17.   The character set.   In order to make TₑX readily portable to a wide variety of computers, all of its input text is converted to an internal eight-bit code that includes standard ASCII, the "American Standard Code for Information Interchange." This conversion is done immediately when each character is read in. Conversely, characters are converted from ASCII to the user's external representation just before they are output to a text file.

Such an internal code is relevant to users of TₑX primarily because it governs the positions of characters in the fonts. For example, the character 'A' has ASCII code 65 = 0101, and when TₑX typesets this letter it specifies character number 65 in the current font. If that font actually has 'A' in a different position, TₑX doesn't know what the real position is; the program that does the actual printing from TₑX's device-independent files is responsible for converting from ASCII to a particular font encoding.

TₑX's internal code also defines the value of constants that begin with a reverse apostrophe; and it provides an index to the \catcode, \mathcode, \uccode, \lccode, and \delcode tables.

18.   Characters of text that have been converted to TₑX's internal form are said to be of type *ASCII_code*, which is a subrange of the integers.

⟨ Types in the outer block 18 ⟩ ≡
  typedef uint8_t ASCII_code;   ▷ eight-bit numbers ◁

See also sections 25, 38, 101, 109, 113, 150, 212, 269, 300, 548, 594, 920, 925, 1410, and 1640.

This code is used in section 4.

19.   The original Pascal compiler was designed in the late 60s, when six-bit character sets were common, so it did not make provision for lowercase letters. Nowadays, of course, we need to deal with both capital and small letters in a convenient way, especially in a program for typesetting; so the present specification of TₑX has been written under the assumption that the Pascal compiler and run-time system permit the use of text files with more than 64 distinguishable characters. More precisely, we assume that the character set contains at least the letters and symbols associated with ASCII codes 040 through 0176; all of these characters are now available on most computer terminals.

Since we are dealing with more characters than were present in the first Pascal compilers, we have to decide what to call the associated data type. Some Pascals use the original name **unsigned char** for the characters in text files, even though there now are more than 64 such characters, while other Pascals consider **unsigned char** to be a 64-element subrange of a larger data type that has some other name.

In order to accommodate this difference, we shall use the name **text_char** to stand for the data type of the characters that are converted to and from **ASCII_code** when they are input and output. We shall also assume that **text_char** consists of the elements *chr*(*first_text_char*) through *chr*(*last_text_char*), inclusive. The following definitions should be adjusted if necessary.

#**define text_char unsigned char**   ▷ the data type of characters in text files ◁
#**define** *first_text_char* 0   ▷ ordinal number of the smallest element of **text_char** ◁
#**define** *last_text_char* 255   ▷ ordinal number of the largest element of **text_char** ◁

⟨ Local variables for initialization 19 ⟩ ≡
  int *i*;

See also sections 163 and 927.

This code is used in section 4.

20.   The TₑX processor converts between ASCII code and the user's external character set by means of arrays *xord* and *xchr* that are analogous to Pascal's *ord* and *chr* functions.

⟨ Global variables 13 ⟩ +≡
  static ASCII_code *xord*[256];   ▷ specifies conversion of input characters ◁
  static text_char *xchr*[256];   ▷ specifies conversion of output characters ◁

21.   Since we are assuming that our Pascal system is able to read and write the visible characters of standard ASCII (although not necessarily using the ASCII codes to represent them), the following assignment statements initialize the standard part of the *xchr* array properly, without needing any system-dependent changes. On the other hand, it is possible to implement TeX with less complete character sets, and in such cases it will be necessary to change something here.

⟨ Set initial values of key variables 21 ⟩ ≡
$xchr[°40] ← '␣'; \; xchr[°41] ← '!'; \; xchr[°42] ← '"'; \; xchr[°43] ← '\#'; \; xchr[°44] ← '\$';$
$xchr[°45] ← '\%'; \; xchr[°46] ← '\&'; \; xchr[°47] ← '\backslash'';$
$xchr[°50] ← '('; \; xchr[°51] ← ')'; \; xchr[°52] ← '*'; \; xchr[°53] ← '+'; \; xchr[°54] ← ',';$
$xchr[°55] ← '-'; \; xchr[°56] ← '.'; \; xchr[°57] ← '/';$
$xchr[°60] ← '0'; \; xchr[°61] ← '1'; \; xchr[°62] ← '2'; \; xchr[°63] ← '3'; \; xchr[°64] ← '4';$
$xchr[°65] ← '5'; \; xchr[°66] ← '6'; \; xchr[°67] ← '7';$
$xchr[°70] ← '8'; \; xchr[°71] ← '9'; \; xchr[°72] ← ':'; \; xchr[°73] ← ';'; \; xchr[°74] ← '<';$
$xchr[°75] ← '='; \; xchr[°76] ← '>'; \; xchr[°77] ← '?';$
$xchr[°100] ← '@'; \; xchr[°101] ← 'A'; \; xchr[°102] ← 'B'; \; xchr[°103] ← 'C'; \; xchr[°104] ← 'D';$

This code is used in section 8.

22.   Some of the ASCII codes without visible characters have been given symbolic names in this program because they are used with a special meaning.

#**define** *null_code* °0   ▷ ASCII code that might disappear ◁
#**define** *carriage_return* °15   ▷ ASCII code used at end of line ◁
#**define** *invalid_code* °177   ▷ ASCII code that many systems prohibit in text files ◁

23.   The ASCII code is "standard" only to a certain extent, since many computer installations have found it advantageous to have ready access to more than 94 printing characters. Appendix C of *The TeXbook* gives a complete specification of the intended correspondence between characters and TeX's internal representation.

   If TeX is being used on a garden-variety Pascal for which only standard ASCII codes will appear in the input and output files, it doesn't really matter what codes are specified in $xchr[0 .. °37]$, but the safest policy is to blank everything out by using the code shown below.

   However, other settings of $xchr$ will make TeX more friendly on computers that have an extended character set, so that users can type things like '$\neq$' instead of '\ne'. People with extended character sets can assign codes arbitrarily, giving an $xchr$ equivalent to whatever characters the users of TeX are allowed to have in their input files. It is best to make the codes correspond to the intended interpretations as shown in Appendix C whenever possible; but this is not necessary. For example, in countries with an alphabet of more than 26 letters, it is usually best to map the additional letters into codes less than 040. To get the most "permissive" character set, change '␣' on the right of these assignment statements to $chr(i)$.

⟨ Set initial values of key variables 21 ⟩ +≡
    for $(i \leftarrow 0;\ i \leq °37;\ i{+}{+})\ xchr[i] \leftarrow chr(i);$ ▷ TeX Live ◁
    for $(i \leftarrow °177;\ i \leq °377;\ i{+}{+})\ xchr[i] \leftarrow chr(i);$ ▷ TeX Live ◁

24.   The following system-independent code makes the $xord$ array contain a suitable inverse to the information in $xchr$. Note that if $xchr[i] \equiv xchr[j]$ where $i < j < °177$, the value of $xord[xchr[i]]$ will turn out to be j or more; hence, standard ASCII code numbers will be used instead of codes below 040 in case there is a coincidence.

⟨ Set initial values of key variables 21 ⟩ +≡
    for $(i \leftarrow first\_text\_char;\ i \leq last\_text\_char;\ i{+}{+})\ xord[chr(i)] \leftarrow invalid\_code;$
    for $(i \leftarrow °200;\ i \leq °377;\ i{+}{+})\ xord[xchr[i]] \leftarrow i;$
    for $(i \leftarrow 0;\ i \leq °176;\ i{+}{+})\ xord[xchr[i]] \leftarrow i;$

25. Input and output.   The bane of portability is the fact that different operating systems treat input and output quite differently, perhaps because computer scientists have not given sufficient attention to this problem. People have felt somehow that input and output are not part of "real" programming. Well, it is true that some kinds of programming are more fun than others. With existing input/output conventions being so diverse and so messy, the only sources of joy in such parts of the code are the rare occasions when one can find a way to make the program a little less bad than it might have been. We have two choices, either to attack I/O now and get it over with, or to postpone I/O until near the end. Neither prospect is very attractive, so let's get it over with.

The basic operations we need to do are (1) inputting and outputting of text, to or from a file or the user's terminal; (2) inputting and outputting of eight-bit bytes, to or from a file; (3) instructing the operating system to initiate ("open") or to terminate ("close") input or output from a specified file; (4) testing whether the end of an input file has been reached.

TeX needs to deal with two kinds of files. We shall use the term **alpha_file** for a file that contains textual data, and the term **byte_file** for a file that contains eight-bit binary information. These two types turn out to be the same on many computers, but sometimes there is a significant distinction, so we shall be careful to distinguish between them. Standard protocols for transferring such files from computer to computer, via high-speed networks, are now becoming available to more and more communities of users.

The program actually makes use also of a third kind of file, called a **word_file**, when dumping and reloading base information for its own initialization. We shall define a word file later; but it will be possible for us to specify simple operations on word files before they are defined.

⟨ Types in the outer block 18 ⟩ +≡
    typedef uint8_t eight_bits;   ▷ unsigned one-byte quantity ◁
    typedef struct { **FILE** ∗*f*; **text_char** *d*; } **alpha_file**;   ▷ files that contain textual data ◁
    typedef struct { **FILE** ∗*f*; **eight_bits** *d*; } **byte_file**;   ▷ files that contain binary data ◁

26.   Most of what we need to do with respect to input and output can be handled by the I/O facilities that are standard in Pascal, i.e., the routines called *get*, *put*, *eof*, and so on. But standard Pascal does not allow file variables to be associated with file names that are determined at run time, so it cannot be used to implement TeX; some sort of extension to Pascal's ordinary *reset* and *rewrite* is crucial for our purposes. We shall assume that *name_of_file* is a variable of an appropriate type such that the Pascal run-time system being used to implement TeX can open a file whose external name is specified by *name_of_file*.

⟨ Global variables 13 ⟩ +≡
    static unsigned char *name_of_file0* [*file_name_size* +1] ← {0}, ∗**const** *name_of_file* ← *name_of_file0* −1;
        ▷ on some systems this may be a **record** variable ◁

    static int *name_length*;   ▷ this many characters are actually relevant in *name_of_file* (the rest are blank) ◁

27.   To open files, TEX used Pascal's *reset* function. We use the `kpathsearch` library to implement new functions in the section on TEX Live Integration. Here we give only the function prototypes.

TEX's file-opening functions do not issue their own error messages if something goes wrong. If a file identified by *name_of_file* cannot be found, or if such a file cannot be opened for some other reason (e.g., someone may already be trying to write the same file) TEX's file-opening functions return *false*. This allows TEX to undertake appropriate corrective action.

static FILE *∗open_in*(**char** *∗filename*, **kpse_file_format_type** *t*, **const char** *∗rwb*);   ▷ TEX Live ◁
static bool *a_open_in*(**alpha_file** *∗f*);   ▷ open a text file for input ◁
static bool *b_open_in*(**byte_file** *∗f*);   ▷ open a binary file for input ◁
static bool *w_open_in*(**word_file** *∗f*);   ▷ open a word file for input ◁
static FILE *∗open_out*(**const char** *∗file_name*, **const char** *∗file_mode*);   ▷ TEX Live ◁
static bool *a_open_out*(**alpha_file** *∗f*);   ▷ open a text file for output ◁
static bool *b_open_out*(**byte_file** *∗f*);   ▷ open a binary file for output ◁
#ifdef INIT
static bool *w_open_out*(**word_file** *∗f*);   ▷ open a word file for output ◁
#endif

28.   Files can be closed with the Pascal-H routine '*pascal_close*(*f*)', which should be used when all input or output with respect to *f* has been completed. This makes *f* available to be opened again, if desired; and if *f* was used for output, the *pascal_close* operation makes the corresponding external file appear on the user's area, ready to be read.

These procedures should not generate error messages if a file is being closed before it has been successfully opened.

static void *a_close*(**alpha_file** *∗f*)   ▷ close a text file ◁
{ *pascal_close*((*∗f*));
}
static void *b_close*(**byte_file** *∗f*)   ▷ close a binary file ◁
{ *pascal_close*((*∗f*));
}
static void *w_close*(**word_file** *∗f*)   ▷ close a word file ◁
{ *pascal_close*((*∗f*));
}

29.   Binary input and output are done with Pascal's ordinary *get* and *put* procedures, so we don't have to make any other special arrangements for binary I/O. Text output is also easy to do with standard Pascal routines. The treatment of text input is more difficult, however, because of the necessary translation to **ASCII_code** values. TEX's conventions should be efficient, and they should blend nicely with the user's operating environment.

30.   Input from text files is read one line at a time, using a routine called *input_ln*. This function is defined in terms of global variables called *buffer*, *first*, and *last* that will be described in detail later; for now, it suffices for us to know that *buffer* is an array of **ASCII_code** values, and that *first* and *last* are indices into this array representing the beginning and ending of a line of text.

⟨ Global variables 13 ⟩ +≡
static ASCII_code *buffer*[*buf_size* + 1];   ▷ lines of characters being read ◁
static int *first*;   ▷ the first unused position in *buffer* ◁
static int *last*;   ▷ end of the line just input to *buffer* ◁
static int *max_buf_stack*;   ▷ largest index used in *buffer* ◁

31.   The *input_ln* function brings the next line of input from the specified file into available positions of the buffer array and returns the value *true*, unless the file has already been entirely read, in which case it returns *false* and sets *last* ← *first*. In general, the **ASCII_code** numbers that represent the next line of the file are input into *buffer*[*first*], *buffer*[*first* + 1], ..., *buffer*[*last* − 1]; and the global variable *last* is set equal to *first* plus the length of the line. Trailing blanks are removed from the line; thus, either *last* ≡ *first* (in which case the line was entirely blank) or *buffer*[*last* − 1] ≠ '␣'.

An overflow error is given, however, if the normal actions of *input_ln* would make *last* ≥ *buf_size*; this is done so that other parts of TEX can safely look at the contents of *buffer*[*last* + 1] without overstepping the bounds of the *buffer* array. Upon entry to *input_ln*, the condition *first* < *buf_size* will always hold, so that there is always room for an "empty" line.

The variable *max_buf_stack*, which is used to keep track of how large the *buf_size* parameter must be to accommodate the present job, is also kept up to date by *input_ln*.

If the *bypass_eoln* parameter is *true*, *input_ln* will do a *get* before looking at the first character of the line; this skips over an *eoln* that was in *f.d*. The procedure does not do a *get* when it reaches the end of the line; therefore it can be used to acquire input from the user's terminal as well as from ordinary text files.

Standard Pascal says that a file should have *eoln* immediately before *eof*, but TEX needs only a weaker restriction: If *eof* occurs in the middle of a line, the system function *eoln* should return a *true* result (even though *f.d* will be undefined).

Since the inner loop of *input_ln* is part of TEX's "inner loop"—each character of input comes in at this place—it is wise to reduce system overhead by making use of special routines that read in an entire array of characters at once, if such routines are available. The following code uses standard Pascal to illustrate what needs to be done, but finer tuning is often possible at well-developed Pascal sites.

```
static bool input_ln(alpha_file *f, bool bypass_eoln)        ▷ inputs the next line or returns false ◁
{ int last_nonblank;      ▷ last with trailing blanks removed ◁

  if (bypass_eoln)
    if (¬eof((*f))) get((*f));        ▷ input the first character of the line into f.d ◁
  last ← first;       ▷ cf. Matthew 19 : 30 ◁
  if (eof((*f))) return false;
  else { last_nonblank ← first;
    while (¬eoln((*f))) { if (last ≥ max_buf_stack) { max_buf_stack ← last + 1;
        if (max_buf_stack ≡ buf_size) ⟨ Report overflow of the input buffer, and abort 35 ⟩;
      }
      buffer[last] ← xord[(*f).d]; get((*f)); incr(last);
      if (buffer[last − 1] ≠ '␣') last_nonblank ← last;
    }
    last ← last_nonblank; return true;
  }
}
```

32.   The user's terminal acts essentially like other files of text, except that it is used both for input and for output. When the terminal is considered an input file, the file variable is called *term_in*, and when it is considered an output file the file variable is *term_out*.

⟨ Global variables 13 ⟩ +≡
```
  static alpha_file term_in;      ▷ the terminal as an input file ◁
  static alpha_file term_out;       ▷ the terminal as an output file ◁
```

33.   Here is how to open the terminal files in Pascal-H. The '/I' switch suppresses the first *get*.

#**define** *t_open_in*   *term_in.f* ← *stdin*   ▷ open the terminal for text input ◁
#**define** *t_open_out*   *term_out.f* ← *stdout*   ▷ open the terminal for text output ◁

34.   Sometimes it is necessary to synchronize the input/output mixture that happens on the user's terminal, and three system-dependent procedures are used for this purpose. The first of these, *update_terminal*, is called when we want to make sure that everything we have output to the terminal so far has actually left the computer's internal buffers and been sent. The second, *clear_terminal*, is called when we wish to cancel any input that the user may have typed ahead (since we are about to issue an unexpected error message). The third, *wake_up_terminal*, is supposed to revive the terminal if the user has disabled it by some instruction to the operating system. The following macros show how these operations can be specified in Pascal-H:

#**define** *update_terminal*   *fflush*(*term_out.f*)   ▷ empty the terminal output buffer ◁
#**define** *clear_terminal*   *fflush*(*term_in.f*)   ▷ clear the terminal input buffer ◁
#**define** *wake_up_terminal*   *do_nothing*   ▷ cancel the user's cancellation of output ◁

35.   We need a special routine to read the first line of TEX input from the user's terminal. This line is different because it is read before we have opened the transcript file; there is sort of a "chicken and egg" problem here. If the user types '\input paper' on the first line, or if some macro invoked by that line does such an \input, the transcript file will be named 'paper.log'; but if no \input commands are performed during the first line of terminal input, the transcript file will acquire its default name 'texput.log'. (The transcript file will not contain error messages generated by the first line before the first \input command.)

The first line is even more special if we are lucky enough to have an operating system that treats TEX differently from a run-of-the-mill Pascal object program. It's nice to let the user start running a TEX job by typing a command line like 'tex paper'; in such a case, TEX will operate as if the first line of input were 'paper', i.e., the first line will consist of the remainder of the command line, after the part that invoked TEX.

The first line is special also because it may be read before TEX has input a format file. In such cases, normal error messages cannot yet be given. The following code uses concepts that will be explained later. (If the Pascal compiler does not support non-local **goto**, the statement '**goto** *exit*(0)' should be replaced by something that quietly terminates the program.)

⟨ Report overflow of the input buffer, and abort 35 ⟩ ≡
  if (*format_ident* ≡ 0) { *write_ln*(*term_out*, "Buffer␣size␣exceeded!"); *exit*(0);
  }
  else { *cur_input.loc_field* ← *first*; *cur_input.limit_field* ← *last* − 1; *overflow*("buffer␣size", *buf_size*);
  }

This code is used in sections 31, 1440, and 1887.

36.   Different systems have different ways to get started. But regardless of what conventions are adopted, the routine that initializes the terminal should satisfy the following specifications:

  1) It should open file *term_in* for input from the terminal. (The file *term_out* will already be open for output to the terminal.)
  2) If the user has given a command line, this line should be considered the first line of terminal input. Otherwise the user should be prompted with '******', and the first line of input should be whatever is typed in response.
  3) The first line of input, which might or might not be a command line, should appear in locations *first* to *last* − 1 of the *buffer* array.
  4) The global variable *loc* should be set so that the character to be read next by TEX is in *buffer*[*loc*]. This character should not be blank, and we should have *loc* < *last*.

(It may be necessary to prompt the user several times before a non-blank line comes in. The prompt is '******' instead of the later '*****' because the meaning is slightly different: '\input' need not be typed immediately after '******'.)

#**define** *loc*   *cur_input.loc_field*   ▷ location of first unread character in *buffer* ◁

37.   The following routine calls *input_command_line* to retrieve a possible command line.

```
static bool init_terminal(void)      ▷ gets the terminal input started ◁
{ t_open_in;
  if (input_command_line()) return true;      ▷ TEX Live ◁
  loop { wake_up_terminal; pascal_write(term_out, "**"); update_terminal;
    if (¬input_ln(&term_in, true))      ▷ this shouldn't happen ◁
    { write_ln(term_out); pascal_write(term_out, "!␣End␣of␣file␣on␣the␣terminal...␣why?");
      return false;
    }
    loc ← first;
    while ((loc < last) ∧ (buffer[loc] ≡ '␣')) incr(loc);
    if (loc < last) { return true;      ▷ return unless the line was all blank ◁
    }
    write_ln(term_out, "Please␣type␣the␣name␣of␣your␣input␣file.");
  }
}
```

38.   String handling.   Control sequence names and diagnostic messages are variable-length strings of eight-bit characters. Since Pascal does not have a well-developed string mechanism, TeX does all of its string processing by homegrown methods.

Elaborate facilities for dynamic strings are not needed, so all of the necessary operations can be handled with a simple data structure. The array *str_pool* contains all of the (eight-bit) ASCII codes in all of the strings, and the array *str_start* contains indices of the starting points of each string. Strings are referred to by integer numbers, so that string number s comprises the characters $str\_pool[j]$ for $str\_start[s] \leq j < str\_start[s+1]$. Additional integer variables *pool_ptr* and *str_ptr* indicate the number of entries used so far in *str_pool* and *str_start*, respectively; locations $str\_pool[pool\_ptr]$ and $str\_start[str\_ptr]$ are ready for the next string to be allocated.

String numbers 0 to 255 are reserved for strings that correspond to single ASCII characters. This is in accordance with the conventions of `WEB`, which converts single-character strings into the ASCII code number of the single character involved, while it converts other strings into integers and builds a string pool file. Thus, when the string constant `"."` appears in the program below, `WEB` converts it into the integer 46, which is the ASCII code for a period, while `WEB` will convert a string like `"hello"` into some integer greater than 255. String number 46 will presumably be the single character '.'; but some ASCII codes have no standard visible representation, and TeX sometimes needs to be able to print an arbitrary ASCII character, so the first 256 strings are used to specify exactly what should be printed for each of the 256 possibilities.

Elements of the *str_pool* array must be ASCII codes that can actually be printed; i.e., they must have an *xchr* equivalent in the local character set. (This restriction applies only to preloaded strings, not to those generated dynamically by the user.)

Some Pascal compilers won't pack integers into a single byte unless the integers lie in the range $-128 \mathrel{..} 127$. To accommodate such systems we access the string pool only via macros that can easily be redefined.

#**define** $si(A)$ A ▷ convert from **ASCII_code** to *packed_ASCII_code* ◁
#**define** $so(A)$ A ▷ convert from *packed_ASCII_code* to **ASCII_code** ◁

⟨ Types in the outer block 18 ⟩ +≡
    typedef int32_t pool_pointer;   ▷ for variables that point into *str_pool* ◁
    typedef int32_t str_number;   ▷ for variables that point into *str_start* ◁
    typedef uint8_t packed_ASCII_code;   ▷ elements of *str_pool* array ◁

39.   ⟨ Global variables 13 ⟩ +≡
    static packed_ASCII_code $str\_pool[pool\_size + 1]$;   ▷ the characters ◁
    static pool_pointer $str\_start[max\_strings + 1]$;   ▷ the starting pointers ◁
    static pool_pointer $pool\_ptr$;   ▷ first unused position in *str_pool* ◁
    static str_number str_ptr;   ▷ number of the current string being created ◁
    static pool_pointer $init\_pool\_ptr$;   ▷ the starting value of *pool_ptr* ◁
    static str_number $init\_str\_ptr$;   ▷ the starting value of *str_ptr* ◁

40.   Several of the elementary string operations are performed using `WEB` macros instead of Pascal procedures, because many of the operations are done quite frequently and we want to avoid the overhead of procedure calls. For example, here is a simple macro that computes the length of a string.

#**define** $length(A)$ $(str\_start[A+1] - str\_start[A])$ ▷ the number of characters in string number # ◁

41.   The length of the current string is called *cur_length*:
#**define** cur_length $(pool\_ptr - str\_start[str\_ptr])$

42.   Strings are created by appending character codes to *str_pool*. The *append_char* macro, defined here, does not check to see if the value of *pool_ptr* has gotten too high; this test is supposed to be made before *append_char* is used. There is also a *flush_char* macro, which erases the last character appended.

   To test if there is room to append *l* more characters to *str_pool*, we shall write *str_room*(*l*), which aborts TeX and gives an apologetic error message if there isn't enough room.

#**define** *append_char*(*A*)   ▷ put **ASCII_code** # at the end of *str_pool* ◁
          { *str_pool*[*pool_ptr*] ← *si*(*A*); *incr*(*pool_ptr*);
          }
#**define** *flush_char*   *decr*(*pool_ptr*)   ▷ forget the last character in the pool ◁
#**define** *str_room*(*A*)   ▷ make sure that the pool hasn't overflowed ◁
          { **if** (*pool_ptr* + *A* > *pool_size*) *overflow*("pool␣size", *pool_size* − *init_pool_ptr*);
          }

43.   Once a sequence of characters has been appended to *str_pool*, it officially becomes a string when the function *make_string* is called. This function returns the identification number of the new string as its value.

   static str_number *make_string*(**void**)   ▷ current string enters the pool ◁
   { **if** (*str_ptr* ≡ *max_strings*) *overflow*("number␣of␣strings", *max_strings* − *init_str_ptr*);
     incr(*str_ptr*); *str_start*[*str_ptr*] ← *pool_ptr*; **return** *str_ptr* − 1;
   }

44.   To destroy the most recently made string, we say *flush_string*.

#**define** *flush_string*
          { *decr*(*str_ptr*); *pool_ptr* ← *str_start*[*str_ptr*];
          }

45.   The following subroutine compares string *s* with another string of the same length that appears in *buffer* starting at position *k*; the result is *true* if and only if the strings are equal. Empirical tests indicate that *str_eq_buf* is used in such a way that it tends to return *true* about 80 percent of the time.

   static bool *str_eq_buf*(**str_number** *s*, **int** *k*)   ▷ test equality of strings ◁
   {   ▷ loop exit ◁
     pool_pointer *j*;   ▷ running index ◁
     bool *result*;   ▷ result of comparison ◁

     j ← *str_start*[*s*];
     while (*j* < *str_start*[*s* + 1]) { **if** (*so*(*str_pool*[*j*]) ≠ *buffer*[*k*]) { *result* ← *false*; **goto** *not_found*;
       }
       incr(*j*); *incr*(*k*);
     }
     result ← *true*;
   not_found: **return** *result*;
   }

46.   Here is a similar routine, but it compares two strings in the string pool, and it does not assume that they have the same length.

> **static bool** str_eq_str(**str_number** s, **str_number** t)   ▷ test equality of strings ◁
> {   ▷ loop exit ◁
>   **pool_pointer** j, k;   ▷ running indices ◁
>   **bool** $result$;   ▷ result of comparison ◁
>
> $result \leftarrow false$;
>   **if** $(length(s) \neq length(t))$ **goto** not_found;
> $j \leftarrow str\_start[s]$; $k \leftarrow str\_start[t]$;
>   **while** $(j < str\_start[s+1])$ { **if** $(str\_pool[j] \neq str\_pool[k])$ **goto** not_found;
> $incr(j)$; $incr(k)$;
>   }
> $result \leftarrow true$;
> not_found: **return** $result$;
> }

⟨ Declare PRₒTE procedures for strings 1566 ⟩

47.   The initial values of str_pool, str_start, $pool\_ptr$, and str_ptr are computed by the INITEX program, based in part on the information that WEB has output while processing TₑX.

> **static bool** $get\_strings\_started$(**void**)   ▷ initializes the string pool ◁

> }

This code is used in section 47.

49.   The first 128 strings will contain 95 standard ASCII characters, and the other 33 characters will be printed in three-symbol form like '`^^A`' unless a system-dependent change is made here. Installations that have an extended character set, where for example $xchr[°32] \equiv \text{´#´}$, would like string 032 to be the single character 032 instead of the three characters 0136, 0136, 0132 (`^^Z`). On the other hand, even people with an extended character set will want to represent string 015 by `^^M`, since 015 is *carriage_return*; the idea is to produce visible strings instead of tabs or line-feeds or carriage-returns or bell-rings or characters that are treated anomalously in text files.

   Unprintable characters of codes 128–255 are, similarly, rendered `^^80`–`^^ff`.

   The boolean expression defined here should be *true* unless TEX internal code number k corresponds to a non-troublesome visible symbol in the local character set. An appropriate formula for the extended character set recommended in *The TEXbook* would, for example, be '$k \in [0, °10 \mathbin{..} °12, °14, °15, °33, °177 \mathbin{..} °377]$'. If character k cannot be printed, and $k < °200$, then character $k + °100$ or $k - °100$ must be printable; moreover, ASCII codes $[°41 \mathbin{..} °46, °60 \mathbin{..} °71, °136, °141 \mathbin{..} °146, °160 \mathbin{..} °171]$ must be printable. Thus, at least 80 printable characters are needed.

⟨ Character k cannot be printed 49 ⟩ ≡
    $(k < \text{'}{}_\sqcup\text{'}) \lor (k > \text{'}{\sim}\text{'})$

This code is used in section 48.

50.   The *pool_file* variable is no longer needed and has been removed.

   Instead of reading the other strings from the `TEX.POOL` file, it is sufficient here to add the empty string.

⟨ Add the empty string to the string pool 50 ⟩ ≡
    make_string( );

This code is used in section 47.

51.   Without a string pool file there is no need for a pool check sum either. But this is a convenient place to define the function *s_no* that will add literal strings to the string pool at runtime, thereby obtaining their string number.

```
static int s_no(const char *str)
{ if (str[0] ≡ 0) return empty_string;
  if (str[1] ≡ 0) return str[0];
  str_room(strlen(str));
  while (*str ≠ 0) append_char(*str ++);
  return make_string( );
}
```

52.   The function *s_no* is used in *initialize* and needs a forward declaration.

⟨ Forward declarations 52 ⟩ ≡
    static int *s_no*(**const char** *∗str*);

See also sections 1562, 1564, 1695, 1716, 1848, 1854, 1867, 1871, and 1888.

This code is used in section 4.

53.   (Empty section to keep numbering intact.)

54. On-line and off-line printing.   Messages that are sent to a user's terminal and to the transcript-log file are produced by several '*print*' procedures. These procedures will direct their output to a variety of places, based on the setting of the global variable *selector*, which has the following possible values:

term_and_log, the normal setting, prints on the terminal and on the transcript file.

log_only, prints only on the transcript file.

term_only, prints only on the terminal.

no_print, doesn't print at all. This is used only in rare cases before the transcript file is open.

pseudo, puts output into a cyclic buffer that is used by the *show_context* routine; when we get to that routine we shall discuss the reasoning behind this curious mode.

new_string, appends the output to the current string in the string pool.

0 to 15, prints on one of the sixteen files for \write output.

The symbolic names '*term_and_log*', etc., have been assigned numeric codes that satisfy the convenient relations $no\_print + 1 \equiv term\_only$, $no\_print + 2 \equiv log\_only$, $term\_only + 2 \equiv log\_only + 1 \equiv term\_and\_log$.

Three additional global variables, *tally* and *term_offset* and *file_offset*, record the number of characters that have been printed since they were most recently cleared to zero. We use *tally* to record the length of (possibly very long) stretches of printing; *term_offset* and *file_offset*, on the other hand, keep track of how many characters have appeared so far on the current line that has been output to the terminal or to the transcript file, respectively.

#**define** *no_print* 16   ▷ *selector* setting that makes data disappear ◁

#**define** *term_only* 17   ▷ printing is destined for the terminal only ◁

See also sections 61, 528, and 533.

This code is used in section 1332.

56. Macro abbreviations for output to the terminal and to the log file are defined here for convenience. Some systems need special conventions for terminal output, and it is possible to adhere to those conventions by changing *wterm*, *wterm_ln*, and *wterm_cr* in this section.

This code is used in section 4.

57. To end a line of text output, we call *print_ln*.

⟨ Basic printing procedures 56 ⟩ +≡
  static void *print_ln*(**void**)   ▷ prints an end-of-line ◁
  { **switch** (*selector*) {
    case *term_and_log*:
      { *wterm_cr*; *wlog_cr*; *term_offset* ← 0; *file_offset* ← 0;
      } **break**;
    case *log_only*:
      { *wlog_cr*; *file_offset* ← 0;
      } **break**;
    case *term_only*:
      { *wterm_cr*; *term_offset* ← 0;
      } **break**;
    case *no_print*: **case** *pseudo*: **case** *new_string*: *do_nothing*; **break**;
    default: *write_ln*(*write_file*[*selector*]);
    }
  }   ▷ *tally* is not affected ◁

58.   The *print_char* procedure sends one character to the desired destination, using the *xchr* array to map it into an external character compatible with *input_ln*. All printing comes through *print_ln* or *print_char*.

⟨ Basic printing procedures 56 ⟩ +≡
  static void *print_char*(**ASCII_code** *s*)   ▷ prints a single character ◁
  { **if** (⟨ Character *s* is the current new-line character 244 ⟩)
      if (*selector* < *pseudo*) { *print_ln*( ); **return**;
      }
    switch (*selector*) {
    case *term_and_log*:
      { *wterm*("%c", *xchr*[*s*]); *wlog*("%c", *xchr*[*s*]); *incr*(*term_offset*); *incr*(*file_offset*);
        if (*term_offset* ≡ *max_print_line*) { *wterm_cr*; *term_offset* ← 0;
        }
        if (*file_offset* ≡ *max_print_line*) { *wlog_cr*; *file_offset* ← 0;
        }
      } **break**;
    case *log_only*:
      { *wlog*("%c", *xchr*[*s*]); *incr*(*file_offset*);
        if (*file_offset* ≡ *max_print_line*) *print_ln*( );
      } **break**;
    case *term_only*:
      { *wterm*("%c", *xchr*[*s*]); *incr*(*term_offset*);
        if (*term_offset* ≡ *max_print_line*) *print_ln*( );
      } **break**;
    case *no_print*: *do_nothing*; **break**;
    case *pseudo*:
      if (*tally* < *trick_count*) *trick_buf*[*tally* % *error_line*] ← *s*; **break**;
    case *new_string*:
      { **if** (*pool_ptr* < *pool_size*) *append_char*(*s*);
      } **break**;   ▷ we drop characters if the string space is full ◁
    default: *pascal_write*(*write_file*[*selector*], "%c", *xchr*[*s*]);
    }
    incr(*tally*);
  }

59.   An entire string is output by calling *print*. Note that if we are outputting the single standard ASCII character c, we could call *print*('c'), since 'c' ≡ 99 is the number of a single-character string, as explained above. But *print_char*('c') is quicker, so TeX goes directly to the *print_char* routine when it knows that this is safe. (The present implementation assumes that it is always safe to print a visible ASCII character.)

⟨ Basic printing procedures 56 ⟩ +≡
    static void *print*(**char** *∗s*)   ▷ the simple version ◁
    { **if** (*s* ≡ Λ) *s* ← "???";   ▷ this can't happen ◁
      while (*∗s* ≠ 0) *print_char*(*∗s++*); }
    static void *printn*(**int** *s*)   ▷ prints string *s* ◁
    { **pool_pointer** *j*;   ▷ current character code position ◁
      int *nl*;   ▷ new-line character to restore ◁
      if (*s* ≥ *str_ptr*) {
        print("???"); **return**;
      }   ▷ this can't happen ◁
      else if (*s* < 256)
        if (*s* < 0) {
          print("???"); **return**;
        }   ▷ can't happen ◁
        else { **if** (*selector* > *pseudo*) { *print_char*(*s*); **return**;   ▷ internal strings are not expanded ◁
          }
          if ((⟨ Character *s* is the current new-line character 244 ⟩))
            if (*selector* < *pseudo*) { *print_ln*( ); **return**;
            }
          nl ← *new_line_char*; *new_line_char* ← −1;   ▷ temporarily disable new-line character ◁
          j ← *str_start*[*s*];
          while (*j* < *str_start*[*s* + 1]) { *print_char*(*so*(*str_pool*[*j*])); *incr*(*j*);
          }
          new_line_char ← *nl*; **return**;
        }
      j ← *str_start*[*s*];
      while (*j* < *str_start*[*s* + 1]) { *print_char*(*so*(*str_pool*[*j*])); *incr*(*j*);
      }
    }

60.   Control sequence names, file names, and strings constructed with \string might contain **ASCII_code** values that can't be printed using *print_char*. Therefore we use *slow_print* for them:

⟨ Basic printing procedures 56 ⟩ +≡
    static void *slow_print*(**int** *s*)   ▷ prints string *s* ◁
    { **pool_pointer** *j*;   ▷ current character code position ◁
      if ((*s* ≥ *str_ptr*) ∨ (*s* < 256)) *printn*(*s*);
      else { *j* ← *str_start*[*s*];
        while (*j* < *str_start*[*s* + 1]) { *printn*(*so*(*str_pool*[*j*])); *incr*(*j*);
        }
      }
    }

61.   Here is the very first thing that TEX prints: a headline that identifies the version number and format package. The *term_offset* variable is temporarily incorrect, but the discrepancy is not serious since we assume that this part of the program is system dependent.

According to the conventions of TEX Live, we print the *dump_name* if no format identifier is known.

⟨ Initialize the output routines 55 ⟩ +≡
   wterm(**"%s"**, *banner*);
   if (*format_ident* ≡ 0) *wterm_ln*(**"␣(preloaded␣format=%s)"**, *dump_name*);
   else { *slow_print*(*format_ident*); *print_ln*( );
   }
   update_terminal;

62.   The procedure *print_nl* is like *print*, but it makes sure that the string appears at the beginning of a new line.

⟨ Basic printing procedures 56 ⟩ +≡
   static void *print_nl*(**char** *s)   ▷ prints string *s* at beginning of line ◁
   { **if** (((*term_offset* > 0) ∧ (*odd*(*selector*))) ∨ ((*file_offset* > 0) ∧ (*selector* ≥ *log_only*))) *print_ln*( );
     print(*s*);
   }

63.   The procedure *print_esc* prints a string that is preceded by the user's escape character (which is usually a backslash).

⟨ Basic printing procedures 56 ⟩ +≡
   static void *printn_esc*(**str_number** *s*)   ▷ prints escape character, then *s* ◁
   { **int** *c*;   ▷ the escape character code ◁

    ⟨ Set variable *c* to the current escape character 243 ⟩;
    if (*c* ≥ 0)
      if (*c* < 256) *printn*(*c*);
    slow_print(*s*);
   }
   static void *print_esc*(**char** *s*)   ▷ the fast way ◁
   { **int** *c*;   ▷ the escape character code ◁

    ⟨ Set variable *c* to the current escape character 243 ⟩;
    if (*c* ≥ 0)
      if (*c* < 256) *printn*(*c*);
    print(*s*);
   }

64.   An array of digits in the range 0 . . 15 is printed by *print_the_digs*.

⟨ Basic printing procedures 56 ⟩ +≡
   static void *print_the_digs*(**eight_bits** *k*)   ▷ prints *dig*[*k* − 1] . . . *dig*[0] ◁
   { **while** (*k* > 0) { *decr*(*k*);
     if (*dig*[*k*] < 10) *print_char*(**'0'** + *dig*[*k*]);
     else *print_char*(**'A'** − 10 + *dig*[*k*]);
   }
   }

65.   The following procedure, which prints out the decimal representation of a given integer n, has been written carefully so that it works properly if $n \equiv 0$ or if $(-n)$ would cause overflow. It does not apply % or / to negative arguments, since such operations are not implemented consistently by all Pascal compilers.

⟨ Basic printing procedures 56 ⟩ +≡
   static void *print_int*(**int** n)   ▷ prints an integer in decimal form ◁
   { **int** k;   ▷ index to current digit; we assume that $|n| < 10^{23}$ ◁
     int m;   ▷ used to negate n in possibly dangerous cases ◁

     $k \leftarrow 0$;
     if $(n < 0)$ { *print_char*(`'-'`);
       if $(n > -100000000)$ *negate*(n);
       else { $m \leftarrow -1 - n$; $n \leftarrow m/10$; $m \leftarrow (m \% 10) + 1$; $k \leftarrow 1$;
         if $(m < 10)$ *dig*$[0] \leftarrow m$;
         else { *dig*$[0] \leftarrow 0$; *incr*(n);
         }
       }
     }
     do {
       dig$[k] \leftarrow n \% 10$; $n \leftarrow n/10$; *incr*(k);
     } **while** $(\neg(n \equiv 0))$;
     print_the_digs(k);
   }

66.   Here is a trivial procedure to print two digits; it is usually called with a parameter in the range $0 \le n \le 99$.

   static void *print_two*(**int** n)   ▷ prints two least significant digits ◁
   { $n \leftarrow abs(n) \% 100$; *print_char*(`'0'` + $(n/10)$); *print_char*(`'0'` + $(n \% 10)$);
   }

67.   Hexadecimal printing of nonnegative integers is accomplished by *print_hex*.

   static void *print_hex*(**int** n)   ▷ prints a positive integer in hexadecimal form ◁
   { **int** k;   ▷ index to current digit; we assume that $0 \le n < 16^{22}$ ◁

     $k \leftarrow 0$; *print_char*(`'"'`);
     do {
       dig$[k] \leftarrow n \% 16$; $n \leftarrow n/16$; *incr*(k);
     } **while** $(\neg(n \equiv 0))$;
     print_the_digs(k);
   }

68.   Old versions of TEX needed a procedure called *print_ASCII* whose function is now subsumed by *print*. We retain the old name here as a possible aid to future software archæologists.

#**define** *print_ASCII* *printn*

69.   Roman numerals are produced by the *print_roman_int* routine. Readers who like puzzles might enjoy trying to figure out how this tricky code works; therefore no explanation will be given. Notice that 1990 yields `mcmxc`, not `mxm`.

> **static void** *print_roman_int*(**int** *n*)
> { **pool_pointer** *j, k*;   ▷ mysterious indices into *mystery* ◁
>   **nonnegative_integer** *u, v*;   ▷ mysterious numbers ◁
>   **const char** *mystery*[ ] ← "m2d5c2l5x2v5i";
>
>   *j* ← 0; *v* ← 1000;
>   **loop** { **while** (*n* ≥ *v*) { *print_char*(*so*(*mystery*[*j*])); *n* ← *n* − *v*;
>   }
>   **if** (*n* ≤ 0) **return**;   ▷ nonpositive input produces no output ◁
>   *k* ← *j* + 2; *u* ← *v*/(*so*(*mystery*[*k* − 1]) − '0');
>   **if** (*mystery*[*k* − 1] ≡ *si*('2')) { *k* ← *k* + 2; *u* ← *u*/(*so*(*mystery*[*k* − 1]) − '0');
>   }
>   **if** (*n* + *u* ≥ *v*) { *print_char*(*so*(*mystery*[*k*])); *n* ← *n* + *u*;
>   }
>   **else** { *j* ← *j* + 2; *v* ← *v*/(*so*(*mystery*[*j* − 1]) − '0');
>   }
>   }
> }

70.   The *print* subroutine will not print a string that is still being created. The following procedure will.

> **static void** *print_current_string*(**void**)   ▷ prints a yet-unmade string ◁
> { **pool_pointer** *j*;   ▷ points to current character code ◁
>
>   *j* ← *str_start*[*str_ptr*];
>   **while** (*j* < *pool_ptr*) { *print_char*(*so*(*str_pool*[*j*])); *incr*(*j*);
>   }
> }

71.   Here is a procedure that asks the user to type a line of input, assuming that the *selector* setting is either *term_only* or *term_and_log*. The input is placed into locations *first* through *last* − 1 of the *buffer* array, and echoed on the transcript file if appropriate.

This procedure is never called when *interaction* < *scroll_mode*.

> #**define** *prompt_input*(*A*)
>   { *wake_up_terminal*; *print*(*A*); *term_input*( );
>   }   ▷ prints a string and gets a line of input ◁
> **static void** *term_input*(**void**)   ▷ gets a line from the terminal ◁
> { **int** *k*;   ▷ index into *buffer* ◁
>
>   *update_terminal*;   ▷ now the user sees the prompt for sure ◁
>   **if** (¬*input_ln*(&*term_in*, *true*)) *fatal_error*("End␣of␣file␣on␣the␣terminal!");
>   *term_offset* ← 0;   ▷ the user's line ended with ⟨return⟩ ◁
>   *decr*(*selector*);   ▷ prepare to echo the input ◁
>   **if** (*last* ≠ *first*)
>   **for** (*k* ← *first*; *k* ≤ *last* − 1; *k*++) *printn*(*buffer*[*k*]);
>   *print_ln*( ); *incr*(*selector*);   ▷ restore previous status ◁
> }

72.   Reporting errors.   When something anomalous is detected, TEX typically does something like this:

$$print\_err("\texttt{Something}_{⊔}\texttt{anomalous}_{⊔}\texttt{has}_{⊔}\texttt{been}_{⊔}\texttt{detected}");$$
$$help3("\texttt{This}_{⊔}\texttt{is}_{⊔}\texttt{the}_{⊔}\texttt{first}_{⊔}\texttt{line}_{⊔}\texttt{of}_{⊔}\texttt{my}_{⊔}\texttt{offer}_{⊔}\texttt{to}_{⊔}\texttt{help.}")$$
$$("\texttt{This}_{⊔}\texttt{is}_{⊔}\texttt{the}_{⊔}\texttt{second}_{⊔}\texttt{line.}_{⊔}\texttt{I'm}_{⊔}\texttt{trying}_{⊔}\texttt{to}")$$
$$("\texttt{explain}_{⊔}\texttt{the}_{⊔}\texttt{best}_{⊔}\texttt{way}_{⊔}\texttt{for}_{⊔}\texttt{you}_{⊔}\texttt{to}_{⊔}\texttt{proceed.}");$$
$$error(\,);$$

A two-line help message would be given using *help2*, etc.; these informal helps should use simple vocabulary that complements the words used in the official error message that was printed. (Outside the U.S.A., the help messages should preferably be translated into the local vernacular. Each line of help is at most 60 characters long, in the present implementation, so that *max_print_line* will not be exceeded.)

The *print_err* procedure supplies a '!' before the official message, and makes sure that the terminal is awake if a stop is going to occur. The *error* procedure supplies a '.' after the official message, then it shows the location of the error; and if $interaction \equiv error\_stop\_mode$, it also enters into a dialog with the user, during which time the help message may be printed.

⟨ Error handling procedures 72 ⟩ ≡
  static void *print_err*(**char** *∗s*)
  { **if** (*interaction* ≡ *error_stop_mode*) *wake_up_terminal*;
    if (*filelineerrorstylep*) *print_file_line*(\,);   ▷ TEX Live ◁
    else *print_nl*("!⊔");
    print(*s*);
  }

See also sections 78, 81, 82, 93, 94, and 95.

This code is used in section 4.

73.   The global variable *interaction* has four settings, representing increasing amounts of user interaction:

#**define** *batch_mode*   0   ▷ omits all stops and omits terminal output ◁
#**define** *nonstop_mode*   1   ▷ omits all stops ◁
#**define** *scroll_mode*   2   ▷ omits error stops ◁
#**define** *error_stop_mode*   3   ▷ stops at every opportunity to interact ◁

⟨ Global variables 13 ⟩ +≡
  static int *interaction*;   ▷ current level of interaction ◁

74.   ⟨ Set initial values of key variables 21 ⟩ +≡
  if (*interaction_option* < 0) *interaction* ← *error_stop_mode*;
  else *interaction* ← *interaction_option*;   ▷ TEX Live ◁

75.   TEX is careful not to call *error* when the print *selector* setting might be unusual. The only possible values of *selector* at the time of error messages are

no_print (when *interaction* ≡ *batch_mode* and *log_file* not yet open);
term_only (when *interaction* > *batch_mode* and *log_file* not yet open);
log_only (when *interaction* ≡ *batch_mode* and *log_file* is open);
term_and_log (when *interaction* > *batch_mode* and *log_file* is open).

⟨ Initialize the print *selector* based on *interaction* 75 ⟩ ≡
  if (*interaction* ≡ *batch_mode*) *selector* ← *no_print*; **else** *selector* ← *term_only*

This code is used in sections 1265 and 1337.

76.   A global variable *deletions_allowed* is set *false* if the *get_next* routine is active when *error* is called; this ensures that *get_next* and related routines like *get_token* will never be called recursively. A similar interlock is provided by *set_box_allowed*.

The global variable *history* records the worst level of error that has been detected. It has four possible values: *spotless*, *warning_issued*, *error_message_issued*, and *fatal_error_stop*.

Another global variable, *error_count*, is increased by one when an *error* occurs without an interactive dialog, and it is reset to zero at the end of every paragraph. If *error_count* reaches 100, TEX decides that there is no point in continuing further.

#**define** *spotless*   0   ▷ *history* value when nothing has been amiss yet ◁
#**define** *warning_issued*   1   ▷ *history* value when *begin_diagnostic* has been called ◁
#**define** *error_message_issued*   2   ▷ *history* value when *error* has been called ◁
#**define** *fatal_error_stop*   3   ▷ *history* value when termination was premature ◁

⟨ Global variables 13 ⟩ +≡
  static bool *deletions_allowed*;   ▷ is it safe for *error* to call *get_token*? ◁
  static bool *set_box_allowed*;   ▷ is it safe to do a \setbox assignment? ◁
  static int *history*;   ▷ has the source input been clean so far? ◁
  static int *error_count*;   ▷ the number of scrolled errors since the last paragraph ended ◁

77.   The value of *history* is initially *fatal_error_stop*, but it will be changed to *spotless* if TEX survives the initialization process.

⟨ Set initial values of key variables 21 ⟩ +≡
  deletions_allowed ← *true*; *set_box_allowed* ← *true*; *error_count* ← 0;
    ▷ *history* is initialized elsewhere ◁

78.   Since errors can be detected almost anywhere in TEX, we want to declare the error procedures near the beginning of the program. But the error procedures in turn use some other procedures, which need to be declared *forward* before we get to *error* itself.

It is possible for *error* to be called recursively if some error arises when *get_token* is being used to delete a token, and/or if some fatal error occurs while TEX is trying to fix a non-fatal one. But such recursion is never more than two levels deep.

⟨ Error handling procedures 72 ⟩ +≡
  static void *normalize_selector*(**void**);
  static void *get_token*(**void**);
  static void *term_input*(**void**);
  static void *show_context*(**void**);

80.   ⟨ Set initial values of key variables 21 ⟩ +≡
   $help\_ptr \leftarrow 0;$ $use\_err\_help \leftarrow false;$

81.   The $jump\_out$ procedure just cuts across all active procedure levels and goes to end_of_TEX. This is the only nontrivial **goto** statement in the whole program. It is used when there is no recovery from a particular error.

   Some Pascal compilers do not implement non-local **goto** statements. In such cases the body of $jump\_out$ should simply be '$close\_files\_and\_terminate;$' followed by a call on some system procedure that quietly terminates the program.

⟨ Error handling procedures 72 ⟩ +≡
   static void $jump\_out(\mathbf{void})$
   { $close\_files\_and\_terminate();$ $exit(0);$
   }

82.   Here now is the general $error$ routine.

⟨ Error handling procedures 72 ⟩ +≡
   static void $error(\mathbf{void})$ ▷ completes the job of error reporting ◁
   { **ASCII_code** $c;$ ▷ what the user types ◁
      int $s1, s2, s3, s4;$ ▷ used to save global variables when deleting tokens ◁

         $history \leftarrow fatal\_error\_stop;$ $jump\_out();$
      }
      ⟨ Put help message on the transcript file 90 ⟩;
   }

83. ⟨Get user's advice and **return** 83⟩ ≡
  loop { *resume*:
    if (*interaction* ≠ *error_stop_mode*) **return**;
    clear_for_error_prompt( ); *prompt_input*("?␣");
    if (*last* ≡ *first*) **return**;
    c ← *buffer*[*first*];
    if (*c* ≥ 'a') *c* ← *c* + 'A' − 'a';   ▷ convert to uppercase ◁
    ⟨Interpret code *c* and **return** if done 84⟩;
  }

This code is used in section 82.

84.   It is desirable to provide an 'E' option here that gives the user an easy way to return from TEX to the system editor, with the offending line ready to be edited. But such an extension requires some system wizardry, so the present implementation simply types out the name of the file that should be edited and the relevant line number.

There is a secret 'D' option available when the debugging routines haven't been commented out.

⟨Interpret code *c* and **return** if done 84⟩ ≡
  switch (*c*) {
  case '0': **case** '1': **case** '2': **case** '3': **case** '4': **case** '5': **case** '6': **case** '7': **case** '8':
    case '9':
    if (*deletions_allowed*) ⟨Delete *c* − "0" tokens and **goto** *resume* 88⟩ **break**;
#**ifdef** DEBUG

     else { *prompt_input*("insert>"); *loc* ← *first*;
     }
     first ← *last*; *cur_input.limit_field* ← *last* − 1;   ▷ no *end_line_char* ends this line ◁
     return;
   }

This code is used in section 84.

88.   We allow deletion of up to 99 tokens at a time.

⟨Delete *c* − "0" tokens and **goto** *resume* 88⟩ ≡
   { *s1* ← *cur_tok*; *s2* ← *cur_cmd*; *s3* ← *cur_chr*; *s4* ← *align_state*; *align_state* ← 1000000;
     OK_to_interrupt ← *false*;
     if ((*last* > *first* + 1) ∧ (*buffer*[*first* + 1] ≥ '0') ∧ (*buffer*[*first* + 1] ≤ '9'))
        c ← *c* ∗ 10 + *buffer*[*first* + 1] − '0' ∗ 11;
     else *c* ← *c* − '0';
     while (*c* > 0) { *get_token*( );   ▷ one-level recursive call of *error* is possible ◁
       decr(*c*);
     }
     cur_tok ← *s1*; *cur_cmd* ← *s2*; *cur_chr* ← *s3*; *align_state* ← *s4*; *OK_to_interrupt* ← *true*;
     help2("I␣have␣just␣deleted␣some␣text,␣as␣you␣asked.",
     "You␣can␣now␣delete␣more,␣or␣insert,␣or␣whatever."); *show_context*( ); **goto** *resume*;
   }

This code is used in section 84.

89. ⟨Print the help information and **goto** *resume* 89⟩ ≡
  { **if** (*use_err_help*) { *give_err_help*( ); *use_err_help* ← *false*;
    }
    else { **if** (*help_ptr* ≡ 0) *help2*("Sorry,␣I␣don't␣know␣how␣to␣help␣in␣this␣situation.",
        "Maybe␣you␣should␣try␣asking␣a␣human?");
      do {
        decr(*help_ptr*); *print*(*help_line*[*help_ptr*]); *print_ln*( );
      } **while** (¬(*help_ptr* ≡ 0));
    }
    help4("Sorry,␣I␣already␣gave␣what␣help␣I␣could...",
    "Maybe␣you␣should␣try␣asking␣a␣human?",
    "An␣error␣might␣have␣occurred␣before␣I␣noticed␣any␣problems.",
    "''If␣all␣else␣fails,␣read␣the␣instructions.'");
      goto *resume*;
  }

This code is used in section 84.

90. ⟨Put help message on the transcript file 90⟩ ≡
  if (*interaction* > *batch_mode*) *decr*(*selector*);   ▷ avoid terminal output ◁
  if (*use_err_help*) { *print_ln*( ); *give_err_help*( );
  }
  else
    while (*help_ptr* > 0) { *decr*(*help_ptr*); *print_nl*(*help_line*[*help_ptr*]);
    }
  print_ln( );
  if (*interaction* > *batch_mode*) *incr*(*selector*);   ▷ re-enable terminal output ◁
  print_ln( )

This code is used in section 82.

91.   A dozen or so error messages end with a parenthesized integer, so we save a teeny bit of program space by declaring the following procedure:

  static void *int_error*(**int** *n*)
  { *print*("␣("); *print_int*(*n*); *print_char*(')'); *error*( );
  }

92.   In anomalous cases, the print selector might be in an unknown state; the following subroutine is called to fix things just enough to keep running a bit longer.

  static void *normalize_selector*(**void**)
  { **if** (*log_opened*) *selector* ← *term_and_log*;
    else *selector* ← *term_only*;
    if (*job_name* ≡ 0) *open_log_file*( );
    if (*interaction* ≡ *batch_mode*) *decr*(*selector*);
  }

93.   The following procedure prints TEX's last words before dying.

#**define** *succumb*
          { **if** (*interaction* ≡ *error_stop_mode*) *interaction* ← *scroll_mode*;   ▷ no more interaction ◁
            if (*log_opened*) *error* ( );
            if (*interaction* > *batch_mode*) *debug_help* ( );
            history ← *fatal_error_stop*; *jump_out* ( );   ▷ irrecoverable error ◁
          }
⟨Error handling procedures 72⟩ +≡
  static void *fatal_error* (**char** ∗*s*)   ▷ prints *s*, and that's it ◁
  { *normalize_selector* ( );
    print_err ("Emergency␣stop"); *help1* (*s*); *succumb*;
  }

94.   Here is the most dreaded error message.

⟨Error handling procedures 72⟩ +≡
  static void *overflow* (**char** ∗*s*, **int** *n*)   ▷ stop due to finiteness ◁
  { *normalize_selector* ( ); *print_err* ("TeX␣capacity␣exceeded,␣sorry␣["); *print* (*s*); *print_char* ('=');
    print_int (*n*); *print_char* (']'); *help2* ("If␣you␣really␣absolutely␣need␣more␣capacity,",
    "you␣can␣ask␣a␣wizard␣to␣enlarge␣me."); *succumb*;
  }

95.   The program might sometime run completely amok, at which point there is no choice but to stop. If no previous error has been detected, that's bad news; a message is printed that is really intended for the TEX maintenance person instead of the user (unless the user has been particularly diabolical). The index entries for 'this can't happen' may help to pinpoint the problem.

⟨Error handling procedures 72⟩ +≡
  static void *confusion* (**char** ∗*s*)   ▷ consistency check violated; *s* tells where ◁
  { *normalize_selector* ( );
    if (*history* < *error_message_issued*) { *print_err* ("This␣can't␣happen␣("); *print* (*s*);
      print_char (')'); *help1* ("I'm␣broken.␣Please␣show␣this␣to␣someone␣who␣can␣fix␣can␣fix");
    }
    else { *print_err* ("I␣can't␣go␣on␣meeting␣you␣like␣this");
      help2 ("One␣of␣your␣faux␣pas␣seems␣to␣have␣wounded␣me␣deeply...",
      "in␣fact,␣I'm␣barely␣conscious.␣Please␣fix␣it␣and␣try␣again.");
    }
    succumb;
  }

96.   Users occasionally want to interrupt TEX while it's running. If the Pascal runtime system allows this, one can implement a routine that sets the global variable *interrupt* to some nonzero value when such an interrupt is signalled. Otherwise there is probably at least a way to make *interrupt* nonzero using the Pascal debugger.

#**define** *check_interrupt*
          { **if** (*interrupt* ≠ 0) *pause_for_instructions* ( );
          }
⟨Global variables 13⟩ +≡
  static int *interrupt*;   ▷ should TEX pause for instructions? ◁
  static bool *OK_to_interrupt*;   ▷ should interrupts be observed? ◁

97.   ⟨Set initial values of key variables 21⟩ +≡
  interrupt ← 0; *OK_to_interrupt* ← *true*;

98.   When an interrupt has been detected, the program goes into its highest interaction level and lets the user have nearly the full flexibility of the *error* routine. TeX checks for interrupts only at times when it is safe to do this.

> **static void** *pause_for_instructions*(**void**)
> { **if** (*OK_to_interrupt*) { *interaction* ← *error_stop_mode*;
>   **if** ((*selector* ≡ *log_only*) ∨ (*selector* ≡ *no_print*)) *incr*(*selector*);
>   *print_err*("Interruption"); *help3*("You␣rang?",
>   "Try␣to␣insert␣an␣instruction␣for␣me␣(e.g.,␣'I\\showlists'),",
>   "unless␣you␣just␣want␣to␣quit␣by␣typing␣'X'."); *deletions_allowed* ← *false*; *error*();
>   *deletions_allowed* ← *true*; *interrupt* ← 0;
>   }
> }

99. Arithmetic with scaled dimensions.   The principal computations performed by TEX are done entirely in terms of integers less than 2^{31} in magnitude; and divisions are done only when both dividend and divisor are nonnegative. Thus, the arithmetic specified in this program can be carried out in exactly the same way on a wide variety of computers, including some small ones. Why? Because the arithmetic calculations need to be spelled out precisely in order to guarantee that TEX will produce identical output on different machines. If some quantities were rounded differently in different implementations, we would find that line breaks and even page breaks might occur in different places. Hence the arithmetic of TEX has been designed with care, and systems that claim to be implementations of TEX82 should follow precisely the calculations as they appear in the present program.

(Actually there are three places where TEX uses / with a possibly negative numerator. These are harmless; see / in the index. Also if the user sets the \time or the \year to a negative value, some diagnostic information will involve negative-numerator division. The same remarks apply for % as well as for /.)

100.   Here is a routine that calculates half of an integer, using an unambiguous convention with respect to signed odd numbers.

> **static int** *half* (**int** x)
> { **if** (*odd*(x)) **return** $(x + 1)/2$;
>   **else return** $x/2$;
> }

101.   Fixed-point arithmetic is done on *scaled integers* that are multiples of 2^{-16}. In other words, a binary point is assumed to be sixteen bit positions from the right end of a binary computer word.

#**define** *unity* °*200000*   ▷ 2^{16}, represents 1.00000 ◁
#**define** *two* °*400000*   ▷ 2^{17}, represents 2.00000 ◁

⟨ Types in the outer block 18 ⟩ +≡
> **typedef int scaled;**   ▷ this type is used for scaled integers ◁
> **typedef uint32_t nonnegative_integer;**   ▷ $0 \le x < 2^{31}$ ◁
> **typedef int8_t small_number;**   ▷ this type is self-explanatory ◁

102.   The following function is used to create a scaled integer from a given decimal fraction $(.d_0 d_1 \ldots d_{k-1})$, where $0 \le k \le 17$. The digit d_i is given in *dig*[i], and the calculation produces a correctly rounded result.

> **static scaled** *round_decimals* (**small_number** k)   ▷ converts a decimal fraction ◁
> { **int** a;   ▷ the accumulator ◁
>
> $a \leftarrow 0$;
>   **while** ($k > 0$) { *decr*(k); $a \leftarrow (a + dig[k] * two)/10$;
>   }
>   **return** $(a + 1)/2$;
> }

103.   Conversely, here is a procedure analogous to *print_int*. If the output of this procedure is subsequently read by TeX and converted by the *round_decimals* routine above, it turns out that the original value will be reproduced exactly; the "simplest" such decimal number is output, but there is always at least one digit following the decimal point.

The invariant relation in the **repeat** loop is that a sequence of decimal digits yet to be printed will yield the original number if and only if they form a fraction f in the range $s - \delta \leq 10 \cdot 2^{16} f < s$. We can stop if and only if $f = 0$ satisfies this condition; the loop will terminate before s can possibly become zero.

```
static void print_scaled (scaled s)    ▷ prints scaled real, rounded to five digits ◁
{ scaled delta;    ▷ amount of allowable inaccuracy ◁
  if (s < 0) { print_char ('-'); negate (s);    ▷ print the sign, if negative ◁
  }
  print_int (s/unity);    ▷ print the integer part ◁
  print_char ('.'); s ← 10 * (s % unity) + 5; delta ← 10;
  do {
    if (delta > unity) s ← s + °100000 − 50000;    ▷ round the last digit ◁
    print_char ('0' + (s/unity)); s ← 10 * (s % unity); delta ← delta * 10;
  } while (¬(s ≤ delta));
}
```

104.   Physical sizes that a TeX user specifies for portions of documents are represented internally as scaled points. Thus, if we define an 'sp' (scaled point) as a unit equal to 2^{-16} printer's points, every dimension inside of TeX is an integer number of sp. There are exactly 4,736,286.72 sp per inch. Users are not allowed to specify dimensions larger than $2^{30} - 1$ sp, which is a distance of about 18.892 feet (5.7583 meters); two such quantities can be added without overflow on a 32-bit computer.

The present implementation of TeX does not check for overflow when dimensions are added or subtracted. This could be done by inserting a few dozen tests of the form 'if $(x \geq °10000000000)$ *report_overflow*', but the chance of overflow is so remote that such tests do not seem worthwhile.

TeX needs to do only a few arithmetic operations on scaled quantities, other than addition and subtraction, and the following subroutines do most of the work. A single computation might use several subroutine calls, and it is desirable to avoid producing multiple error messages in case of arithmetic overflow; so the routines set the global variable *arith_error* to *true* instead of reporting errors directly to the user. Another global variable, *rem*, holds the remainder after a division.

⟨ Global variables 13 ⟩ +≡
```
static bool arith_error;    ▷ has arithmetic overflow occurred recently? ◁
static scaled rem;    ▷ amount subtracted to get an exact division ◁
```

105.   The first arithmetical subroutine we need computes $nx + y$, where x and y are **scaled** and n is an integer. We will also use it to multiply integers.

```
#define nx_plus_y (A, B, C)   mult_and_add (A, B, C, °7777777777)
#define mult_integers (A, B)   mult_and_add (A, B, 0, °17777777777)
  static scaled mult_and_add (int n, scaled x, scaled y, scaled max_answer)
  { if (n < 0) { negate (x); negate (n);
    }
    if (n ≡ 0) return y;
    else if (((x ≤ (max_answer − y)/n) ∧ (−x ≤ (max_answer + y)/n))) return n * x + y;
    else { arith_error ← true; return 0;
    }
  }
```

106.   We also need to divide scaled dimensions by integers.

```
static scaled x_over_n(scaled x, int n)
{ bool negative;      ▷ should rem be negated? ◁
  scaled x_over_n;

  negative ← false;
  if (n ≡ 0) { arith_error ← true; x_over_n ← 0; rem ← x;
  }
  else { if (n < 0) { negate(x); negate(n); negative ← true;
    }
    if (x ≥ 0) { x_over_n ← x/n; rem ← x % n;
    }
    else { x_over_n ← −((−x)/n); rem ← −((−x) % n);
    }
  }
  if (negative) negate(rem);
  return x_over_n;
}
```

107.   Then comes the multiplication of a scaled number by a fraction $n/(\textbf{double})\, d$, where n and d are nonnegative integers $\leq 2^{16}$ and d is positive. It would be too dangerous to multiply by n and then divide by d, in separate operations, since overflow might well occur; and it would be too inaccurate to divide by d and then multiply by n. Hence this subroutine simulates 1.5-precision arithmetic.

```
static scaled xn_over_d(scaled x, int n, int d)
{ bool positive;      ▷ was x ≥ 0? ◁
  nonnegative_integer t, u, v;      ▷ intermediate quantities ◁
  scaled xn_over_d;

  if (x ≥ 0) positive ← true;
  else { negate(x); positive ← false;
  }
  t ← (x % °100000) * n;  u ← (x/°100000) * n + (t/°100000);  v ← (u % d) * °100000 + (t % °100000);
  if (u/d ≥ °100000) arith_error ← true;
  else u ← °100000 * (u/d) + (v/d);
  if (positive) { xn_over_d ← u; rem ← v % d;
  }
  else { xn_over_d ← −u; rem ← −(v % d);
  }
  return xn_over_d;
}
```

108.   The next subroutine is used to compute the "badness" of glue, when a total t is supposed to be made from amounts that sum to s. According to *The TeXbook*, the badness of this situation is $100(t/s)^3$; however, badness is simply a heuristic, so we need not squeeze out the last drop of accuracy when computing it. All we really want is an approximation that has similar properties.

The actual method used to compute the badness is easier to read from the program than to describe in words. It produces an integer value that is a reasonably close approximation to $100(t/s)^3$, and all implementations of TeX should use precisely this method. Any badness of 2^{13} or more is treated as infinitely bad, and represented by 10000.

It is not difficult to prove that

$$badness(t+1, s) \geq badness(t, s) \geq badness(t, s+1).$$

The badness function defined here is capable of computing at most 1095 distinct values, but that is plenty.

#**define** $\mathit{inf\_bad}$ 10000   ▷ infinitely bad value ◁

⟨ Declare PRoTE arithmetic routines 1637 ⟩

static halfword $badness(\textbf{scaled } t, \textbf{scaled } s)$ ▷ compute badness, given $t \geq 0$ ◁

{ **int** r;   ▷ approximation to $\alpha t/s$, where $\alpha^3 \approx 100 \cdot 2^{18}$ ◁

   if $(t \equiv 0)$ **return** 0;

   else if $(s \leq 0)$ **return** $\mathit{inf\_bad}$;

   else { **if** $(t \leq 7230584)$ $r \leftarrow (t * 297)/s$;   ▷ $297^3 = 99.94 \times 2^{18}$ ◁

   else if $(s \geq 1663497)$ $r \leftarrow t/(s/297)$;

   else $r \leftarrow t$;

   if $(r > 1290)$ **return** $\mathit{inf\_bad}$;   ▷ $1290^3 < 2^{31} < 1291^3$ ◁

   else return $(r * r * r + {}^\circ\mathit{400000})/{}^\circ\mathit{1000000}$;

   }   ▷ that was $r^3/2^{18}$, rounded to the nearest integer ◁

}

109.   When TeX "packages" a list into a box, it needs to calculate the proportionality ratio by which the glue inside the box should stretch or shrink. This calculation does not affect TeX's decision making, so the precise details of rounding, etc., in the glue calculation are not of critical importance for the consistency of results on different computers.

We shall use the type **glue_ratio** for such proportionality ratios. A glue ratio should take the same amount of memory as an **int** (usually 32 bits) if it is to blend smoothly with TeX's other data structures. Thus **glue_ratio** should be equivalent to *short_real* in some implementations of Pascal. Alternatively, it is possible to deal with glue ratios using nothing but fixed-point arithmetic; see *TUGboat* **3**,1 (March 1982), 10–27. (But the routines cited there must be modified to allow negative glue ratios.)

#**define** $set\_glue\_ratio\_zero(A)$ $A \leftarrow 0.0$ ▷ store the representation of zero ratio ◁

#**define** $set\_glue\_ratio\_one(A)$ $A \leftarrow 1.0$ ▷ store the representation of unit ratio ◁

#**define** $\mathit{unfix}(A)$ $((\textbf{double})(A))$ ▷ convert from **glue_ratio** to type **double** ◁

#**define** $\mathit{fix}(A)$ $((\textbf{glue\_ratio})(A))$ ▷ convert from **double** to type **glue_ratio** ◁

#**define** $\mathit{float\_constant}(A)$ $((\textbf{double})(A))$ ▷ convert **int** constant to **double** ◁

#**define** **perror** $e@\&r@\&r@\&o@\&r$ ▷ this is a CWEB coding trick: ◁

   format perror error ▷ '**perror**' will be equivalent to '**error**' ◁

   format error x ▷ but '*error*' will not be treated as a reserved word ◁

⟨ Types in the outer block 18 ⟩ +≡

#**if** __SIZEOF_FLOAT__ $\equiv 4$

   typedef float float32_t;

#**else**

#**perror** float type must have size 4

#**endif**

   typedef float glue_ratio;   ▷ one-word representation of a glue expansion factor ◁

110.   Packed data.   In order to make efficient use of storage space, TeX bases its major data structures on a *memory_word*, which contains either a (signed) integer, possibly scaled, or a (signed) **glue_ratio**, or a small number of fields that are one half or one quarter of the size used for storing integers.

If x is a variable of type *memory_word*, it contains up to four fields that can be referred to as follows:

$$
\begin{array}{ll}
x.i & \text{(an \textbf{int})} \\
x.sc & \text{(a \textbf{scaled} integer)} \\
x.gr & \text{(a \textbf{glue\_ratio})} \\
x.hh.lh,\ x.hh.rh & \text{(two halfword fields)} \\
x.hh.b0,\ x.hh.b1,\ x.hh.rh & \text{(two quarterword fields, one halfword field)} \\
x.qqqq.b0,\ x.qqqq.b1,\ x.qqqq.b2,\ x.qqqq.b3 & \text{(four quarterword fields)}
\end{array}
$$

This is somewhat cumbersome to write, and not very readable either, but macros will be used to make the notation shorter and more transparent. The Pascal code below gives a formal definition of *memory_word* and its subsidiary types, using packed variant records. TeX makes no assumptions about the relative positions of the fields within a word.

Since we are assuming 32-bit integers, a halfword must contain at least 16 bits, and a quarterword must contain at least 8 bits. But it doesn't hurt to have more bits; for example, with enough 36-bit words you might be able to have *mem_max* as large as 262142, which is eight times as much memory as anybody had during the first four years of TeX's existence.

N.B.: Valuable memory space will be dreadfully wasted unless TeX is compiled by a Pascal that packs all of the *memory_word* variants into the space of a single integer. This means, for example, that **glue_ratio** words should be *short_real* instead of **double** on some computers. Some Pascal compilers will pack an integer whose subrange is '0 .. 255' into an eight-bit field, but others insist on allocating space for an additional sign bit; on such systems you can get 256 values into a quarterword only if the subrange is '−128 .. 127'.

The present implementation tries to accommodate as many variations as possible, so it makes few assumptions. If integers having the subrange '*min_quarterword* .. *max_quarterword*' can be packed into a quarterword, and if integers having the subrange '*min_halfword* .. *max_halfword*' can be packed into a halfword, everything should work satisfactorily.

It is usually most efficient to have $min\_quarterword \equiv min\_halfword \equiv 0$, so one should try to achieve this unless it causes a severe problem. The values defined here are recommended for most 32-bit computers.

#**define** *min_quarterword*   0   ▷ smallest allowable value in a *quarterword* ◁
#**define** *max_quarterword*   65535   ▷ largest allowable value in a *quarterword* ◁
#**define** *min_halfword*   0   ▷ smallest allowable value in a **halfword** ◁
#**define** *max_halfword*   #3FFFFFFF   ▷ largest allowable value in a **halfword** ◁

111.   Here are the inequalities that the quarterword and halfword values must satisfy (or rather, the inequalities that they mustn't satisfy):

$\langle$ Check the "constant" values for consistency 14 $\rangle$ $+\equiv$
#**ifdef** INIT
   if $((mem\_min \neq mem\_bot) \vee (mem\_max \neq mem\_top))$ $bad \leftarrow 10$;
#**endif**
   if $((mem\_min > mem\_bot) \vee (mem\_max < mem\_top))$ $bad \leftarrow 10$;
   if $((min\_quarterword > 0) \vee (max\_quarterword < 127))$ $bad \leftarrow 11$;
   if $((min\_halfword > 0) \vee (max\_halfword < 32767))$ $bad \leftarrow 12$;
   if $((min\_quarterword < min\_halfword) \vee (max\_quarterword > max\_halfword))$ $bad \leftarrow 13$;
   if $((mem\_min < min\_halfword) \vee (mem\_max \geq max\_halfword) \vee$
         $(mem\_bot - mem\_min > max\_halfword + 1))$ $bad \leftarrow 14$;
   if $((font\_base < min\_quarterword) \vee (font\_max > max\_quarterword))$ $bad \leftarrow 15$;
   if $(font\_max > font\_base + 256)$ $bad \leftarrow 16$;
   if $((save\_size > max\_halfword) \vee (max\_strings > max\_halfword))$ $bad \leftarrow 17$;
   if $(buf\_size > max\_halfword)$ $bad \leftarrow 18$;
   if $(max\_quarterword - min\_quarterword < 255)$ $bad \leftarrow 19$;

112.   The operation of adding or subtracting $min\_quarterword$ occurs quite frequently in TEX, so it is convenient to abbreviate this operation by using the macros qi and qo for input and output to and from quarterword format.

   The inner loop of TEX will run faster with respect to compilers that don't optimize expressions like '$x + 0$' and '$x - 0$', if these macros are simplified in the obvious way when $min\_quarterword \equiv 0$.

#**define** $qi(A)$ $A + min\_quarterword$ $\triangleright$ to put an **eight_bits** item into a quarterword $\triangleleft$
#**define** $qo(A)$ $A - min\_quarterword$ $\triangleright$ to take an **eight_bits** item out of a quarterword $\triangleleft$
#**define** $hi(A)$ $A + min\_halfword$ $\triangleright$ to put a sixteen-bit item into a halfword $\triangleleft$
#**define** $ho(A)$ $A - min\_halfword$ $\triangleright$ to take a sixteen-bit item from a halfword $\triangleleft$

113.   The reader should study the following definitions closely:

#**define** *sc*   *i*   ▷ **scaled** data is equivalent to **int** ◁

⟨ Types in the outer block 18 ⟩ +≡

  typedef uint16_t quarterword;   ▷ 1/4 of a word ◁

  typedef int32_t halfword;   ▷ 1/2 of a word ◁

  typedef int8_t two_choices;   ▷ used when there are two variants in a record ◁

  typedef int8_t four_choices;   ▷ used when there are four variants in a record ◁

  typedef struct {

    halfword *rh*;

    union {

      halfword *lh*;

      struct {

        quarterword *b0*;

        quarterword *b1*;

      };

    };

  } **two_halves**;

  typedef struct {

    quarterword *b0*;

    quarterword *b1*;

    quarterword *b2*;

    quarterword *b3*;

  } **four_quarters**;

  typedef struct {

    union {

      int *i*;

      glue_ratio *gr*;

      two_halves *hh*;

      four_quarters *qqqq*;

    };

  } **memory_word**;

  typedef struct { **FILE** ∗*f*; **memory_word** *d*; } **word_file**;

114.   When debugging, we may want to print a **memory_word** without knowing what type it is; so we print it in all modes.

#**ifdef** DEBUG

  static void *print_word*(**memory_word** *w*)   ▷ prints *w* in all ways ◁

  { *print_int*(*w.i*); *print_char*(´␣´);

    print_scaled(*w.sc*); *print_char*(´␣´);

    print_scaled(*round*(*unity* ∗ *unfix*(*w.gr*))); *print_ln*( );

    print_int(*w.hh.lh*); *print_char*(´=´); *print_int*(*w.hh.b0*); *print_char*(´:´); *print_int*(*w.hh.b1*);

    print_char(´;´); *print_int*(*w.hh.rh*); *print_char*(´␣´);

    print_int(*w.qqqq.b0*); *print_char*(´:´); *print_int*(*w.qqqq.b1*); *print_char*(´:´);

    print_int(*w.qqqq.b2*); *print_char*(´:´); *print_int*(*w.qqqq.b3*);

  }

#**endif**

115.   Dynamic memory allocation.   The TEX system does nearly all of its own memory allocation, so that it can readily be transported into environments that do not have automatic facilities for strings, garbage collection, etc., and so that it can be in control of what error messages the user receives. The dynamic storage requirements of TEX are handled by providing a large array *mem* in which consecutive blocks of words are used as nodes by the TEX routines.

Pointer variables are indices into this array, or into another array called *eqtb* that will be explained later. A pointer variable might also be a special flag that lies outside the bounds of *mem*, so we allow pointers to assume any **halfword** value. The minimum halfword value represents a null pointer. TEX does not assume that $mem[null]$ exists.

#**define pointer halfword**   ▷ a flag or a location in *mem* or *eqtb* ◁
#**define** *null   min_halfword*   ▷ the null pointer ◁

⟨ Global variables 13 ⟩ +≡
  static pointer *temp_ptr*;   ▷ a pointer variable for occasional emergency use ◁

116.   The *mem* array is divided into two regions that are allocated separately, but the dividing line between these two regions is not fixed; they grow together until finding their "natural" size in a particular job. Locations less than or equal to *lo_mem_max* are used for storing variable-length records consisting of two or more words each. This region is maintained using an algorithm similar to the one described in exercise 2.5–19 of *The Art of Computer Programming*. However, no size field appears in the allocated nodes; the program is responsible for knowing the relevant size when a node is freed. Locations greater than or equal to *hi_mem_min* are used for storing one-word records; a conventional **AVAIL** stack is used for allocation in this region.

Locations of *mem* between *mem_bot* and *mem_top* may be dumped as part of preloaded format files, by the **INITEX** preprocessor. Production versions of TEX may extend the memory at both ends in order to provide more space; locations between *mem_min* and *mem_bot* are always used for variable-size nodes, and locations between *mem_top* and *mem_max* are always used for single-word nodes.

The key pointers that govern *mem* allocation have a prescribed order:

$$null \leq mem\_min \leq mem\_bot < lo\_mem\_max < hi\_mem\_min < mem\_top \leq mem\_end \leq mem\_max.$$

Empirical tests show that the present implementation of TEX tends to spend about 9% of its running time allocating nodes, and about 6% deallocating them after their use.

⟨ Global variables 13 ⟩ +≡
  static memory_word *mem0*[*mem_max − mem_min* + 1], ∗**const** *mem* ← *mem0 − mem_min*;
    ▷ the big dynamic storage area ◁
  static pointer *lo_mem_max*;   ▷ the largest location of variable-size memory in use ◁
  static pointer *hi_mem_min*;   ▷ the smallest location of one-word memory in use ◁

117.   In order to study the memory requirements of particular applications, it is possible to prepare a version of TEX that keeps track of current and maximum memory usage. When code between the delimiters #**ifdef STAT** … #**endif** is not "commented out," TEX will run a bit slower but it will report these statistics when *tracing_stats* is sufficiently large.

⟨ Global variables 13 ⟩ +≡
  static int *var_used*, *dyn_used*;   ▷ how much memory is in use ◁
#**ifdef STAT**
#**define** *incr_dyn_used incr*(*dyn_used*)
#**define** *decr_dyn_used decr*(*dyn_used*)
#**else**
#**define** *incr_dyn_used*
#**define** *decr_dyn_used*
#**endif**

118.   Let's consider the one-word memory region first, since it's the simplest.   The pointer variable *mem_end* holds the highest-numbered location of *mem* that has ever been used.   The free locations of *mem* that occur between *hi_mem_min* and *mem_end*, inclusive, are of type **two_halves**, and we write *info*(*p*) and *link*(*p*) for the *lh* and *rh* fields of *mem*[*p*] when it is of this type. The single-word free locations form a linked list

$$avail,\ link(avail),\ link(link(avail)),\ \ldots$$

terminated by *null*.

#**define** *link*(*A*)   *mem*[*A*].*hh*.*rh*   ▷ the *link* field of a memory word ◁
#**define** *info*(*A*)   *mem*[*A*].*hh*.*lh*   ▷ the *info* field of a memory word ◁

⟨ Global variables 13 ⟩ +≡
   static pointer *avail*;   ▷ head of the list of available one-word nodes ◁
   static pointer *mem_end*;   ▷ the last one-word node used in *mem* ◁

119.   If memory is exhausted, it might mean that the user has forgotten a right brace. We will define some procedures later that try to help pinpoint the trouble.

   ⟨ Declare the procedure called *show_token_list* 292 ⟩
   ⟨ Declare the procedure called *runaway* 306 ⟩

120.   The function *get_avail* returns a pointer to a new one-word node whose *link* field is null. However, TeX will halt if there is no more room left.
   If the available-space list is empty, i.e., if *avail* ≡ *null*, we try first to increase *mem_end*. If that cannot be done, i.e., if *mem_end* ≡ *mem_max*, we try to decrease *hi_mem_min*. If that cannot be done, i.e., if *hi_mem_min* ≡ *lo_mem_max* + 1, we have to quit.

   static pointer *get_avail*(**void**)   ▷ single-word node allocation ◁
   { **pointer** *p*;   ▷ the new node being got ◁

      p ← *avail*;   ▷ get top location in the *avail* stack ◁
      if (*p* ≠ *null*) *avail* ← *link*(*avail*);   ▷ and pop it off ◁
      else if (*mem_end* < *mem_max*)   ▷ or go into virgin territory ◁
      { *incr*(*mem_end*); *p* ← *mem_end*;
      }
      else { *decr*(*hi_mem_min*); *p* ← *hi_mem_min*;
         if (*hi_mem_min* ≤ *lo_mem_max*) { *runaway*();
            ▷ if memory is exhausted, display possible runaway text ◁
            overflow("main␣memory␣size", *mem_max* + 1 − *mem_min*);   ▷ quit; all one-word nodes are busy ◁
         }
      }
      link(*p*) ← *null*;   ▷ provide an oft-desired initialization of the new node ◁
#**ifdef** STAT
      incr(*dyn_used*);
#**endif**   ▷ maintain statistics ◁
      return *p*;
   }

121.   Conversely, a one-word node is recycled by calling *free_avail*. This routine is part of TeX's "inner loop," so we want it to be fast.

#**define** *free_avail*(*A*)   ▷ single-word node liberation ◁
         { *link*(*A*) ← *avail*; *avail* ← *A*; *decr_dyn_used*;
         }

122.   There's also a *fast_get_avail* routine, which saves the procedure-call overhead at the expense of extra programming. This routine is used in the places that would otherwise account for the most calls of *get_avail*.

#**define** *fast_get_avail*(A)
           { A ← *avail*;   ▷ avoid *get_avail* if possible, to save time ◁
             if (A ≡ *null*) A ← *get_avail*( );
             else { *avail* ← *link*(A); *link*(A) ← *null*; *incr_dyn_used*;
             }
           }

123.   The procedure *flush_list*(p) frees an entire linked list of one-word nodes that starts at position p.

   static void *flush_list*(**pointer** p)   ▷ makes list of single-word nodes available ◁
   { **pointer** q, r;   ▷ list traversers ◁

     if (p ≠ *null*) { r ← p;
       do {
         q ← r; r ← *link*(r);
#**ifdef** STAT
         decr(*dyn_used*);
#**endif**
       } **while** (¬(r ≡ *null*));   ▷ now q is the last node on the list ◁
       link(q) ← *avail*; *avail* ← p;
     }
   }

124.   The available-space list that keeps track of the variable-size portion of *mem* is a nonempty, doubly-linked circular list of empty nodes, pointed to by the roving pointer *rover*.

   Each empty node has size 2 or more; the first word contains the special value *max_halfword* in its *link* field and the size in its *info* field; the second word contains the two pointers for double linking.

   Each nonempty node also has size 2 or more. Its first word is of type **two_halves**, and its *link* field is never equal to *max_halfword*. Otherwise there is complete flexibility with respect to the contents of its other fields and its other words.

   (We require *mem_max* < *max_halfword* because terrible things can happen when *max_halfword* appears in the *link* field of a nonempty node.)

#**define** *empty_flag*   *max_halfword*   ▷ the *link* of an empty variable-size node ◁
#**define** *is_empty*(A)   (*link*(A) ≡ *empty_flag*)   ▷ tests for empty node ◁
#**define** *node_size*(A)   *info*(A)   ▷ the size field in empty variable-size nodes ◁
#**define** *llink*(A)   *info*(A + 1)   ▷ left link in doubly-linked list of empty nodes ◁
#**define** *rlink*(A)   *link*(A + 1)   ▷ right link in doubly-linked list of empty nodes ◁

⟨Global variables 13⟩ +≡
   static pointer *rover*;   ▷ points to some node in the list of empties ◁

125.   A call to *get_node* with argument s returns a pointer to a new node of size s, which must be 2 or more. The *link* field of the first word of this new node is set to null. An overflow stop occurs if no suitable space exists.

   If *get_node* is called with $s = 2^{30}$, it simply merges adjacent free areas and returns the value *max_halfword*.

   static pointer *get_node*(**int** s)   ▷ variable-size node allocation ◁
   { **pointer** p;   ▷ the node currently under inspection ◁
     pointer q;   ▷ the node physically after node p ◁
     int r;   ▷ the newly allocated node, or a candidate for this honor ◁
     int t;   ▷ temporary register ◁

   restart: $p \leftarrow rover$;   ▷ start at some free node in the ring ◁
     do {
       ⟨ Try to allocate within node p and its physical successors, and **goto** *found* if allocation was possible 127 ⟩;
       $p \leftarrow rlink(p)$;   ▷ move to the next node in the ring ◁
     } **while** ($\neg(p \equiv rover)$);   ▷ repeat until the whole list has been traversed ◁
     if ($s \equiv °10000000000$) { **return** *max_halfword*;
     }
     if ($lo\_mem\_max + 2 < hi\_mem\_min$)
       if ($lo\_mem\_max + 2 \leq mem\_bot + max\_halfword$)
         ⟨ Grow more variable-size memory and **goto** *restart* 126 ⟩;
     overflow("main␣memory␣size", $mem\_max + 1 - mem\_min$);   ▷ sorry, nothing satisfactory is left ◁
   found: $link(r) \leftarrow null$;   ▷ this node is now nonempty ◁
   #**ifdef** STAT
     $var\_used \leftarrow var\_used + s$;   ▷ maintain usage statistics ◁
   #**endif**
     return r;
   }

126.   The lower part of *mem* grows by 1000 words at a time, unless we are very close to going under. When it grows, we simply link a new node into the available-space list. This method of controlled growth helps to keep the *mem* usage consecutive when TEX is implemented on "virtual memory" systems.

⟨ Grow more variable-size memory and **goto** *restart* 126 ⟩ ≡
   { **if** ($hi\_mem\_min - lo\_mem\_max \geq 1998$) $t \leftarrow lo\_mem\_max + 1000$;
     else $t \leftarrow lo\_mem\_max + 1 + (hi\_mem\_min - lo\_mem\_max)/2$;
         ▷ $lo\_mem\_max + 2 \leq t < hi\_mem\_min$ ◁
     $p \leftarrow llink(rover)$; $q \leftarrow lo\_mem\_max$; $rlink(p) \leftarrow q$; $llink(rover) \leftarrow q$;
     if ($t > mem\_bot + max\_halfword$) $t \leftarrow mem\_bot + max\_halfword$;
     $rlink(q) \leftarrow rover$; $llink(q) \leftarrow p$; $link(q) \leftarrow empty\_flag$; $node\_size(q) \leftarrow t - lo\_mem\_max$;
     $lo\_mem\_max \leftarrow t$; $link(lo\_mem\_max) \leftarrow null$; $info(lo\_mem\_max) \leftarrow null$; $rover \leftarrow q$; **goto** *restart*;
   }
This code is used in section 125.

127. Empirical tests show that the routine in this section performs a node-merging operation about 0.75 times per allocation, on the average, after which it finds that $r > p + 1$ about 95% of the time.

$\langle$ Try to allocate within node p and its physical successors, and **goto** *found* if allocation was possible 127 $\rangle \equiv$

#ifdef STAT
    $var\_used \leftarrow var\_used - s;$
#endif $\triangleright$ maintain statistics $\triangleleft$
  $\}$

131.   Just before `INITEX` writes out the memory, it sorts the doubly linked available space list. The list is probably very short at such times, so a simple insertion sort is used. The smallest available location will be pointed to by $rover$, the next-smallest by $rlink(rover)$, etc.

#**ifdef** INIT
  static void $sort\_avail(\textbf{void})$ ▷ sorts the available variable-size nodes by location ◁
  { **pointer** p, q, r;   ▷ indices into mem ◁
    pointer old_rover;   ▷ initial $rover$ setting ◁
    $p \leftarrow get\_node(°10000000000)$;   ▷ merge adjacent free areas ◁
    $p \leftarrow rlink(rover)$; $rlink(rover) \leftarrow max\_halfword$; $old\_rover \leftarrow rover$;
    while $(p \neq old\_rover)$ ⟨ Sort p into the list starting at $rover$ and advance p to $rlink(p)$ 132 ⟩;
    $p \leftarrow rover$;
    while $(rlink(p) \neq max\_halfword)$ { $llink(rlink(p)) \leftarrow p$; $p \leftarrow rlink(p)$;
    }
    $rlink(p) \leftarrow rover$; $llink(rover) \leftarrow p$;
  }
#**endif**

132.   The following **while** loop is guaranteed to terminate, since the list that starts at $rover$ ends with $max\_halfword$ during the sorting procedure.

⟨ Sort p into the list starting at $rover$ and advance p to $rlink(p)$ 132 ⟩ ≡
  if $(p < rover)$ { $q \leftarrow p$; $p \leftarrow rlink(q)$; $rlink(q) \leftarrow rover$; $rover \leftarrow q$;
  }
  else { $q \leftarrow rover$;
    while $(rlink(q) < p)$ $q \leftarrow rlink(q)$;
    $r \leftarrow rlink(p)$; $rlink(p) \leftarrow rlink(q)$; $rlink(q) \leftarrow p$; $p \leftarrow r$;
  }
This code is used in section 131.

133. Data structures for boxes and their friends.   From the computer's standpoint, TEX's chief mission is to create horizontal and vertical lists. We shall now investigate how the elements of these lists are represented internally as nodes in the dynamic memory.

A horizontal or vertical list is linked together by *link* fields in the first word of each node. Individual nodes represent boxes, glue, penalties, or special things like discretionary hyphens; because of this variety, some nodes are longer than others, and we must distinguish different kinds of nodes. We do this by putting a '*type*' field in the first word, together with the link and an optional '*subtype*'.

#**define** $type(A)$ $mem[A].hh.b0$ ▷ identifies what kind of node this is ◁
#**define** $subtype(A)$ $mem[A].hh.b1$ ▷ secondary identification in some cases ◁

134.   A *char_node*, which represents a single character, is the most important kind of node because it accounts for the vast majority of all boxes. Special precautions are therefore taken to ensure that a *char_node* does not take up much memory space. Every such node is one word long, and in fact it is identifiable by this property, since other kinds of nodes have at least two words, and they appear in *mem* locations less than *hi_mem_min*. This makes it possible to omit the *type* field in a *char_node*, leaving us room for two bytes that identify a *font* and a *character* within that font.

Note that the format of a *char_node* allows for up to 256 different fonts and up to 256 characters per font; but most implementations will probably limit the total number of fonts to fewer than 75 per job, and most fonts will stick to characters whose codes are less than 128 (since higher codes are more difficult to access on most keyboards).

Extensions of TEX intended for oriental languages will need even more than 256×256 possible characters, when we consider different sizes and styles of type. It is suggested that Chinese and Japanese fonts be handled by representing such characters in two consecutive *char_node* entries: The first of these has *font* $\equiv$ *font_base*, and its *link* points to the second; the second identifies the font and the character dimensions. The saving feature about oriental characters is that most of them have the same box dimensions. The *character* field of the first *char_node* is a "*charext*" that distinguishes between graphic symbols whose dimensions are identical for typesetting purposes. (See the METAFONT manual.) Such an extension of TEX would not be difficult; further details are left to the reader.

In order to make sure that the *character* code fits in a quarterword, TEX adds the quantity *min_quarterword* to the actual code.

Character nodes appear only in horizontal lists, never in vertical lists.

#**define** $is\_char\_node(A)$ $(A \geq hi\_mem\_min)$ ▷ does the argument point to a *char_node*? ◁
#**define** $font(A)$ $type(A)$ ▷ the font code in a *char_node* ◁
#**define** $character(A)$ $subtype(A)$ ▷ the character code in a *char_node* ◁

135.   An *hlist_node* stands for a box that was made from a horizontal list. Each *hlist_node* is seven words long, and contains the following fields (in addition to the mandatory *type* and *link*, which we shall not mention explicitly when discussing the other node types): The *height* and *width* and *depth* are scaled integers denoting the dimensions of the box. There is also a *shift_amount* field, a scaled integer indicating how much this box should be lowered (if it appears in a horizontal list), or how much it should be moved to the right (if it appears in a vertical list). There is a *list_ptr* field, which points to the beginning of the list from which this box was fabricated; if *list_ptr* is *null*, the box is empty. Finally, there are three fields that represent the setting of the glue: *glue_set*(p) is a word of type **glue_ratio** that represents the proportionality constant for glue setting; *glue_sign*(p) is *stretching* or *shrinking* or *normal* depending on whether or not the glue should stretch or shrink or remain rigid; and *glue_order*(p) specifies the order of infinity to which glue setting applies (*normal*, *fil*, *fill*, or *filll*). The *subtype* field is not used.

#**define** *hlist_node* 0   ▷ *type* of hlist nodes ◁
#**define** *box_node_size* 9   ▷ number of words to allocate for a box, set, or pack node ◁
#**define** *width_offset* 1   ▷ position of *width* field in a box node ◁
#**define** *depth_offset* 2   ▷ position of *depth* field in a box node ◁
#**define** *height_offset* 3   ▷ position of *height* field in a box node ◁
#**define** *width*(A) *mem*$[A + width\_offset].sc$ ▷ width of the box, in sp ◁
#**define** *depth*(A) *mem*$[A + depth\_offset].sc$ ▷ depth of the box, in sp ◁
#**define** *height*(A) *mem*$[A + height\_offset].sc$ ▷ height of the box, in sp ◁
#**define** *shift_amount*(A) *mem*$[A + 4].sc$ ▷ repositioning distance, in sp ◁
#**define** *list_offset* 5   ▷ position of *list_ptr* field in a box node ◁
#**define** *list_ptr*(A) *link*$(A + list\_offset)$ ▷ beginning of the list inside the box ◁
#**define** *glue_order*(A) *subtype*$(A + list\_offset)$ ▷ applicable order of infinity ◁
#**define** *glue_sign*(A) *type*$(A + list\_offset)$ ▷ stretching or shrinking ◁
#**define** *normal* 0   ▷ the most common case when several cases are named ◁
#**define** *stretching* 1   ▷ glue setting applies to the stretch components ◁
#**define** *shrinking* 2   ▷ glue setting applies to the shrink components ◁
#**define** *glue_offset* 6   ▷ position of *glue_set* in a box node ◁
#**define** *glue_set*(A) *mem*$[A + glue\_offset].gr$ ▷ a word of type **glue_ratio** for glue setting ◁

136.   The *new_null_box* function returns a pointer to an *hlist_node* in which all subfields have the values corresponding to '\hbox{}'. (The *subtype* field is set to *min_quarterword*, for historic reasons that are no longer relevant.)

    static pointer *new_null_box*(**void**)   ▷ creates a new box node ◁
    { **pointer** *p*;   ▷ the new node ◁

       p ← *get_node*(*box_node_size*); *type*(*p*) ← *hlist_node*; *subtype*(*p*) ← *min_quarterword*; *width*(*p*) ← 0;
       depth(*p*) ← 0; *height*(*p*) ← 0; *shift_amount*(*p*) ← 0; *list_ptr*(*p*) ← *null*; *glue_sign*(*p*) ← *normal*;
       glue_order(*p*) ← *normal*; *set_glue_ratio_zero*(*glue_set*(*p*)); **return** *p*;
    }

137.   A *vlist_node* is like an *hlist_node* in all respects except that it contains a vertical list.

#**define** *vlist_node* 1   ▷ *type* of vlist nodes ◁

138.   A *rule_node* stands for a solid black rectangle; it has *width*, *depth*, and *height* fields just as in an *hlist_node*. However, if any of these dimensions is -2^{30}, the actual value will be determined by running the rule up to the boundary of the innermost enclosing box. This is called a "running dimension." The *width* is never running in an hlist; the *height* and *depth* are never running in a vlist.

#**define** *rule_node* 2   ▷ *type* of rule nodes ◁
#**define** *rule_node_size* 4   ▷ number of words to allocate for a rule node ◁
#**define** *null_flag* −°10000000000   ▷ -2^{30}, signifies a missing item ◁
#**define** *is_running*(A) $(A \equiv null\_flag)$ ▷ tests for a running dimension ◁

139. A new rule node is delivered by the *new_rule* function. It makes all the dimensions "running," so you have to change the ones that are not allowed to run.

> **static pointer** *new_rule*(**void**)
> { **pointer** *p*;   ▷ the new node ◁
>
>   *p* ← *get_node*(*rule_node_size*); *type*(*p*) ← *rule_node*; *subtype*(*p*) ← 0;   ▷ the *subtype* is not used ◁
>   *width*(*p*) ← *null_flag*; *depth*(*p*) ← *null_flag*; *height*(*p*) ← *null_flag*; **return** *p*;
> }

140.   Insertions are represented by *ins_node* records, where the *subtype* indicates the corresponding box number. For example, '\insert 250' leads to an *ins_node* whose *subtype* is $250 + min\_quarterword$. The *height* field of an *ins_node* is slightly misnamed; it actually holds the natural height plus depth of the vertical list being inserted. The *depth* field holds the *split_max_depth* to be used in case this insertion is split, and the *split_top_ptr* points to the corresponding *split_top_skip*. The *float_cost* field holds the *floating_penalty* that will be used if this insertion floats to a subsequent page after a split insertion of the same class. There is one more field, the *ins_ptr*, which points to the beginning of the vlist for the insertion.

#**define** *ins_node* 3   ▷ *type* of insertion nodes ◁
#**define** *ins_node_size* 5   ▷ number of words to allocate for an insertion ◁
#**define** *float_cost*(*A*) *mem*[*A* + 1].*i*   ▷ the *floating_penalty* to be used ◁
#**define** *ins_ptr*(*A*) *info*(*A* + 4)   ▷ the vertical list to be inserted ◁
#**define** *split_top_ptr*(*A*) *link*(*A* + 4)   ▷ the *split_top_skip* to be used ◁

141.   A *mark_node* has a *mark_ptr* field that points to the reference count of a token list that contains the user's \mark text. In addition there is a *mark_class* field that contains the mark class.

#**define** *mark_node* 4   ▷ *type* of a mark node ◁
#**define** *small_node_size* 2   ▷ number of words to allocate for most node types ◁
#**define** *mark_ptr*(*A*) *link*(*A* + 1)   ▷ head of the token list for a mark ◁
#**define** *mark_class*(*A*) *info*(*A* + 1)   ▷ the mark class ◁

142.   An *adjust_node*, which occurs only in horizontal lists, specifies material that will be moved out into the surrounding vertical list; i.e., it is used to implement TeX's '\vadjust' operation. The *adjust_ptr* field points to the vlist containing this material.

#**define** *adjust_node* 5   ▷ *type* of an adjust node ◁
#**define** *adjust_ptr*(*A*) *mem*[*A* + 1].*i*   ▷ vertical list to be moved out of horizontal list ◁

143.   A *ligature_node*, which occurs only in horizontal lists, specifies a character that was fabricated from the interaction of two or more actual characters. The second word of the node, which is called the *lig_char* word, contains *font* and *character* fields just as in a *char_node*. The characters that generated the ligature have not been forgotten, since they are needed for diagnostic messages and for hyphenation; the *lig_ptr* field points to a linked list of character nodes for all original characters that have been deleted. (This list might be empty if the characters that generated the ligature were retained in other nodes.)

The *subtype* field is 0, plus 2 and/or 1 if the original source of the ligature included implicit left and/or right boundaries.

#**define** *ligature_node* 6   ▷ *type* of a ligature node ◁
#**define** *lig_char*(*A*) *A* + 1   ▷ the word where the ligature is to be found ◁
#**define** *lig_ptr*(*A*) *link*(*lig_char*(*A*))   ▷ the list of characters ◁

144.   The *new_ligature* function creates a ligature node having given contents of the *font*, *character*, and *lig_ptr* fields. We also have a *new_lig_item* function, which returns a two-word node having a given *character* field. Such nodes are used for temporary processing as ligatures are being created.

> **static pointer** *new_ligature*(**quarterword** *f*, **quarterword** *c*, **pointer** *q*)
> { **pointer** *p*;   ▷ the new node ◁
>
> $p \leftarrow get\_node(small\_node\_size)$; $type(p) \leftarrow ligature\_node$; $font(lig\_char(p)) \leftarrow f$;
> $character(lig\_char(p)) \leftarrow c$; $lig\_ptr(p) \leftarrow q$; $subtype(p) \leftarrow 0$; **return** *p*;
> }
> **static pointer** *new_lig_item*(**quarterword** *c*)
> { **pointer** *p*;   ▷ the new node ◁
>
> $p \leftarrow get\_node(small\_node\_size)$; $character(p) \leftarrow c$; $lig\_ptr(p) \leftarrow null$; **return** *p*;
> }

145.   A *disc_node*, which occurs only in horizontal lists, specifies a "discretionary" line break. If such a break occurs at node *p*, the text that starts at *pre_break*(*p*) will precede the break, the text that starts at *post_break*(*p*) will follow the break, and text that appears in the next *replace_count*(*p*) nodes will be ignored. For example, an ordinary discretionary hyphen, indicated by '\-', yields a *disc_node* with *pre_break* pointing to a *char_node* containing a hyphen, $post\_break \equiv null$, and $replace\_count \equiv 0$. All three of the discretionary texts must be lists that consist entirely of character, kern, box, rule, and ligature nodes.

If $pre\_break(p) \equiv null$, the *ex_hyphen_penalty* will be charged for this break. Otherwise the *hyphen_penalty* will be charged. The texts will actually be substituted into the list by the line-breaking algorithm if it decides to make the break, and the discretionary node will disappear at that time; thus, the output routine sees only discretionaries that were not chosen.

#**define** *disc_node* 7   ▷ *type* of a discretionary node ◁
#**define** *replace_count*(*A*) (*subtype*(*A*) & #7F)   ▷ how many subsequent nodes to replace ◁
#**define** *set_replace_count*(*A*, *B*) (*subtype*(*A*) ← (*B*) & #7F)
#**define** *set_auto_disc*(*A*) (*subtype*(*A*) |= #80)
#**define** *is_auto_disc*(*A*) (*subtype*(*A*) & #80)
#**define** *pre_break*(*A*) *llink*(*A*)   ▷ text that precedes a discretionary break ◁
#**define** *post_break*(*A*) *rlink*(*A*)   ▷ text that follows a discretionary break ◁

> **static pointer** *new_disc*(**void**)   ▷ creates an empty *disc_node* ◁
> { **pointer** *p*;   ▷ the new node ◁
>
> $p \leftarrow get\_node(small\_node\_size)$; $type(p) \leftarrow disc\_node$; $set\_replace\_count(p, 0)$; $pre\_break(p) \leftarrow null$;
> $post\_break(p) \leftarrow null$; **return** *p*;
> }

146.   A *whatsit_node* is a wild card reserved for extensions to TeX. The *subtype* field in its first word says what '*whatsit*' it is, and implicitly determines the node size (which must be 2 or more) and the format of the remaining words. When a *whatsit_node* is encountered in a list, special actions are invoked; knowledgeable people who are careful not to mess up the rest of TeX are able to make TeX do new things by adding code at the end of the program. For example, there might be a 'TeXnicolor' extension to specify different colors of ink, and the whatsit node might contain the desired parameters.

The present implementation of TeX treats the features associated with '\write' and '\special' as if they were extensions, in order to illustrate how such routines might be coded. We shall defer further discussion of extensions until the end of this program.

#**define** *whatsit_node* 8   ▷ *type* of special extension nodes ◁

147.   A *math_node*, which occurs only in horizontal lists, appears before and after mathematical formulas. The *subtype* field is *before* before the formula and *after* after it. There is a *width* field, which represents the amount of surrounding space inserted by \mathsurround.

#**define** *math_node* 9   ▷ *type* of a math node ◁
#**define** *before* 0   ▷ *subtype* for math node that introduces a formula ◁
#**define** *after* 1   ▷ *subtype* for math node that winds up a formula ◁

   static pointer *new_math*(**scaled** *w*, **small_number** *s*)
   { **pointer** *p*;   ▷ the new node ◁

     p ← *get_node*(*small_node_size*); *type*(*p*) ← *math_node*; *subtype*(*p*) ← *s*; *width*(*p*) ← *w*; **return** *p*;
   }

148.   TeX makes use of the fact that *hlist_node*, *vlist_node*, *rule_node*, *ins_node*, *mark_node*, *adjust_node*, *ligature_node*, *disc_node*, *whatsit_node*, and *math_node* are at the low end of the type codes, by permitting a break at glue in a list if and only if the *type* of the previous node is less than *math_node*. Furthermore, a node is discarded after a break if its type is *math_node* or more.

#**define** *precedes_break*(*A*) (*type*(*A*) < *math_node*)
#**define** *non_discardable*(*A*) (*type*(*A*) < *math_node*)

149.   A *glue_node* represents glue in a list. However, it is really only a pointer to a separate glue specification, since TeX makes use of the fact that many essentially identical nodes of glue are usually present. If *p* points to a *glue_node*, *glue_ptr*(*p*) points to another packet of words that specify the stretch and shrink components, etc.

   Glue nodes also serve to represent leaders; the *subtype* is used to distinguish between ordinary glue (which is called *normal*) and the three kinds of leaders (which are called *a_leaders*, *c_leaders*, and *x_leaders*). The *leader_ptr* field points to a rule node or to a box node containing the leaders; it is set to *null* in ordinary glue nodes.

   Many kinds of glue are computed from TeX's "skip" parameters, and it is helpful to know which parameter has led to a particular glue node. Therefore the *subtype* is set to indicate the source of glue, whenever it originated as a parameter. We will be defining symbolic names for the parameter numbers later (e.g., *line_skip_code* ≡ 0, *baseline_skip_code* ≡ 1, etc.); it suffices for now to say that the *subtype* of parametric glue will be the same as the parameter number, plus one.

   In math formulas there are two more possibilities for the *subtype* in a glue node: *mu_glue* denotes an \mskip (where the units are scaled mu instead of scaled pt); and *cond_math_glue* denotes the '\nonscript' feature that cancels the glue node immediately following if it appears in a subscript.

#**define** *glue_node* 10   ▷ *type* of node that points to a glue specification ◁
#**define** *cond_math_glue* 98   ▷ special *subtype* to suppress glue in the next node ◁
#**define** *mu_glue* 99   ▷ *subtype* for math glue ◁
#**define** *a_leaders* 100   ▷ *subtype* for aligned leaders ◁
#**define** *c_leaders* 101   ▷ *subtype* for centered leaders ◁
#**define** *x_leaders* 102   ▷ *subtype* for expanded leaders ◁
#**define** *glue_ptr*(*A*) *llink*(*A*)   ▷ pointer to a glue specification ◁
#**define** *leader_ptr*(*A*) *rlink*(*A*)   ▷ pointer to box or rule node for leaders ◁

150.   A glue specification has a halfword reference count in its first word, representing *null* plus the number of glue nodes that point to it (less one). Note that the reference count appears in the same position as the *link* field in list nodes; this is the field that is initialized to *null* when a node is allocated, and it is also the field that is flagged by *empty_flag* in empty nodes.

Glue specifications also contain three **scaled** fields, for the *width*, *stretch*, and *shrink* dimensions. Finally, there are two one-byte fields called *stretch_order* and *shrink_order*; these contain the orders of infinity (*normal*, *fil*, *fill*, or *filll*) corresponding to the stretch and shrink values.

#**define** *glue_spec_size* 4   ▷ number of words to allocate for a glue specification ◁
#**define** *glue_ref_count*(A) *link*(A)   ▷ reference count of a glue specification ◁
#**define** *stretch*(A) *mem*[A + 2].*sc*   ▷ the stretchability of this glob of glue ◁
#**define** *shrink*(A) *mem*[A + 3].*sc*   ▷ the shrinkability of this glob of glue ◁

#**define** *fill* 2   ▷ second-order infinity ◁
#**define** *filll* 3   ▷ third-order infinity ◁
⟨ Types in the outer block 18 ⟩ +≡
　typedef int8_t glue_ord;   ▷ infinity to the 0, 1, 2, or 3 power ◁

151.   Here is a function that returns a pointer to a copy of a glue spec. The reference count in the copy is *null*, because there is assumed to be exactly one reference to the new specification.

　static pointer *new_spec*(**pointer** *p*)   ▷ duplicates a glue specification ◁
　{ **pointer** *q*;   ▷ the new spec ◁

　　q ← *get_node*(*glue_spec_size*);
　　mem[*q*] ← *mem*[*p*]; *glue_ref_count*(*q*) ← *null*;
　　width(*q*) ← *width*(*p*); *stretch*(*q*) ← *stretch*(*p*); *shrink*(*q*) ← *shrink*(*p*); **return** *q*;
　}

152.   And here's a function that creates a glue node for a given parameter identified by its code number; for example, *new_param_glue*(*line_skip_code*) returns a pointer to a glue node for the current \lineskip.

　static pointer *new_param_glue*(**small_number** *n*)
　{ **pointer** *p*;   ▷ the new node ◁
　　pointer *q*;   ▷ the glue specification ◁

　　p ← *get_node*(*small_node_size*); *type*(*p*) ← *glue_node*; *subtype*(*p*) ← *n* + 1; *leader_ptr*(*p*) ← *null*;
　　q ← ⟨ Current *mem* equivalent of glue parameter number *n* 224 ⟩; *glue_ptr*(*p*) ← *q*;
　　incr(*glue_ref_count*(*q*)); **return** *p*;
　}

153.   Glue nodes that are more or less anonymous are created by *new_glue*, whose argument points to a glue specification.

　static pointer *new_glue*(**pointer** *q*)
　{ **pointer** *p*;   ▷ the new node ◁

　　p ← *get_node*(*small_node_size*); *type*(*p*) ← *glue_node*; *subtype*(*p*) ← *normal*; *leader_ptr*(*p*) ← *null*;
　　glue_ptr(*p*) ← *q*; *incr*(*glue_ref_count*(*q*)); **return** *p*;
　}

154.   Still another subroutine is needed: This one is sort of a combination of *new_param_glue* and *new_glue*. It creates a glue node for one of the current glue parameters, but it makes a fresh copy of the glue specification, since that specification will probably be subject to change, while the parameter will stay put. The global variable *temp_ptr* is set to the address of the new spec.

> **static pointer** *new_skip_param*(**small_number** *n*)
> { **pointer** *p*;   ▷ the new node ◁
>
>   *temp_ptr* ← *new_spec*(⟨ Current *mem* equivalent of glue parameter number *n* 224 ⟩);
>   *p* ← *new_glue*(*temp_ptr*); *glue_ref_count*(*temp_ptr*) ← *null*; *subtype*(*p*) ← *n* + 1; **return** *p*;
> }

155.   A *kern_node* has a *width* field to specify a (normally negative) amount of spacing. This spacing correction appears in horizontal lists between letters like A and V when the font designer said that it looks better to move them closer together or further apart. A kern node can also appear in a vertical list, when its '*width*' denotes additional spacing in the vertical direction. The *subtype* is either *normal* (for kerns inserted from font information or math mode calculations) or *explicit* (for kerns inserted from \kern and \/ commands) or *acc_kern* (for kerns inserted from non-math accents) or *mu_glue* (for kerns inserted from \mkern specifications in math formulas).

#**define** *kern_node* 11   ▷ *type* of a kern node ◁
#**define** *explicit* 1   ▷ *subtype* of kern nodes from \kern and \/ ◁
#**define** *acc_kern* 2   ▷ *subtype* of kern nodes from accents ◁

156.   The *new_kern* function creates a kern node having a given width.

> **static pointer** *new_kern*(**scaled** *w*)
> { **pointer** *p*;   ▷ the new node ◁
>
>   *p* ← *get_node*(*small_node_size*); *type*(*p*) ← *kern_node*; *subtype*(*p*) ← *normal*; *width*(*p*) ← *w*;
>   **return** *p*;
> }

157.   A *penalty_node* specifies the penalty associated with line or page breaking, in its *penalty* field. This field is a fullword integer, but the full range of integer values is not used: Any penalty ≥ 10000 is treated as infinity, and no break will be allowed for such high values. Similarly, any penalty ≤ −10000 is treated as negative infinity, and a break will be forced.

#**define** *penalty_node* 12   ▷ *type* of a penalty node ◁
#**define** *inf_penalty* *inf_bad*   ▷ "infinite" penalty value ◁
#**define** *eject_penalty* (−*inf_penalty*)   ▷ "negatively infinite" penalty value ◁
#**define** *penalty*(*A*) *mem*[*A* + 1].*i*   ▷ the added cost of breaking a list here ◁

158.   Anyone who has been reading the last few sections of the program will be able to guess what comes next.

> **static pointer** *new_penalty*(**int** *m*)
> { **pointer** *p*;   ▷ the new node ◁
>
>   *p* ← *get_node*(*small_node_size*); *type*(*p*) ← *penalty_node*; *subtype*(*p*) ← 0;
>   ▷ the *subtype* is not used ◁
>   *penalty*(*p*) ← *m*; **return** *p*;
> }

159.   You might think that we have introduced enough node types by now. Well, almost, but there is one more: An *unset_node* has nearly the same format as an *hlist_node* or *vlist_node*; it is used for entries in \halign or \valign that are not yet in their final form, since the box dimensions are their "natural" sizes before any glue adjustment has been made. The *glue_set* word is not present; instead, we have a *glue_stretch* field, which contains the total stretch of order *glue_order* that is present in the hlist or vlist being boxed. Similarly, the *shift_amount* field is replaced by a *glue_shrink* field, containing the total shrink of order *glue_sign* that is present. The *subtype* field is called *span_count*; an unset box typically contains the data for $qo(span\_count) + 1$ columns. Unset nodes will be changed to box nodes when alignment is completed.

#**define** *unset_node* 13   ▷ *type* for an unset node ◁
#**define** *unset_set_node* 32   ▷ *type* for an unset *set_node* ◁
#**define** *unset_pack_node* 33   ▷ *type* for an unset *pack_node* ◁
#**define** *glue_stretch*(A) *mem*[$A + glue\_offset$]$.sc$ ▷ total stretch in an unset node ◁
#**define** *glue_shrink*(A) *shift_amount*(A)   ▷ total shrink in an unset node ◁
#**define** *span_count*(A) *subtype*(A)   ▷ indicates the number of spanned columns ◁

160.   In fact, there are still more types coming. When we get to math formula processing we will see that a *style_node* has $type \equiv 14$; and a number of larger type codes will also be defined, for use in math mode only.

161.   Warning: If any changes are made to these data structure layouts, such as changing any of the node sizes or even reordering the words of nodes, the *copy_node_list* procedure and the memory initialization code below may have to be changed. Such potentially dangerous parts of the program are listed in the index under 'data structure assumptions'. However, other references to the nodes are made symbolically in terms of the WEB macro definitions above, so that format changes will leave TeX's other algorithms intact.

162.   Memory layout.   Some areas of *mem* are dedicated to fixed usage, since static allocation is more efficient than dynamic allocation when we can get away with it. For example, locations *mem_bot* to *mem_bot* + 3 are always used to store the specification for glue that is '0pt plus 0pt minus 0pt'. The following macro definitions accomplish the static allocation by giving symbolic names to the fixed positions. Static variable-size nodes appear in locations *mem_bot* through *lo_mem_stat_max*, and static single-word nodes appear in locations *hi_mem_stat_min* through *mem_top*, inclusive. It is harmless to let *lig_trick* and *garbage* share the same location of *mem*.

#define *zero_glue* *mem_bot*   ▷ specification for 0pt plus 0pt minus 0pt ◁

This code is used in section 167.

172.   The $search\_mem$ procedure attempts to answer the question "Who points to node p?" In doing so,
it fetches $link$ and $info$ fields of mem that might not be of type **two_halves**. Strictly speaking, this is
undefined in Pascal, and it can lead to "false drops" (words that seem to point to p purely by coincidence).
But for debugging purposes, we want to rule out the places that do *not* point to p, so a few false drops are
tolerable.

#ifdef DEBUG

173. Displaying boxes.   We can reinforce our knowledge of the data structures just introduced by considering two procedures that display a list in symbolic form. The first of these, called *short_display*, is used in "overfull box" messages to give the top-level description of a list. The other one, called *show_node_list*, prints a detailed description of exactly what is in the data structure.

The philosophy of *short_display* is to ignore the fine points about exactly what is inside boxes, except that ligatures and discretionary breaks are expanded. As a result, *short_display* is a recursive procedure, but the recursion is never more than one level deep.

A global variable *font_in_short_display* keeps track of the font code that is assumed to be present when *short_display* begins; deviations from this font will be printed.

⟨ Global variables 13 ⟩ +≡
   static int *font_in_short_display*;   ▷ an internal font number ◁

> }
>
> **static void** *print_mark*(**int** *p*)   ▷ prints token list data in braces ◁
> { *print_char*('{');
>   **if** ((*p* < *hi_mem_min*) ∨ (*p* > *mem_end*)) *print_esc*("CLOBBERED.");
>   **else** *show_token_list*(*link*(*p*), *null*, *max_print_line* − 10);
>   *print_char*('}');
> }
>
> **static void** *print_rule_dimen*(**scaled** *d*)   ▷ prints dimension in rule node ◁
> { **if** (*is_running*(*d*)) *print_char*('*');
>   **else** *print_scaled*(*d*);
> }

177.   Then there is a subroutine that prints glue stretch and shrink, possibly followed by the name of finite units:

> **static void** *print_glue*(**scaled** *d*, **int** *order*, **char** *∗s*)   ▷ prints a glue component ◁
> { *print_scaled*(*d*);
>   **if** ((*order* < *normal*) ∨ (*order* > *filll*)) *print*("foul");
>   **else if** (*order* > *normal*) { *print*("fil");
>   **while** (*order* > *fil*) { *print_char*('l'); *decr*(*order*);
>   }
>   }
>   **else if** (*s* ≠ 0) *print*(*s*);
> }

178.   The next subroutine prints a whole glue specification.

> **static void** *print_spec*(**int** *p*, **char** *∗s*)   ▷ prints a glue specification ◁
> { **if** ((*p* < *mem_min*) ∨ (*p* ≥ *lo_mem_max*)) *print_char*('*');
>   **else** { *print_scaled*(*width*(*p*));
>   **if** (*s* ≠ 0) *print*(*s*);
>   **if** (*stretch*(*p*) ≠ 0) { *print*("␣plus␣"); *print_glue*(*stretch*(*p*), *stretch_order*(*p*), *s*);
>   }
>   **if** (*shrink*(*p*) ≠ 0) { *print*("␣minus␣"); *print_glue*(*shrink*(*p*), *shrink_order*(*p*), *s*);
>   }
>   }
> }

179.   We also need to declare some procedures that appear later in this documentation.

⟨ Declare procedures needed for displaying the elements of mlists 691 ⟩
⟨ Declare the procedure called *print_skip_param* 225 ⟩

```
static void print_xdimen(pointer p)
{
  if (p ≡ null) {
    print_scaled(0); return;
  }
  print_scaled(xdimen_width(p));
  if (xdimen_hfactor(p) ≠ 0) {
    print_char('+'); print_scaled(xdimen_hfactor(p)); print("*hsize");
  }
  if (xdimen_vfactor(p) ≠ 0) {
    print_char('+'); print_scaled(xdimen_vfactor(p)); print("*vsize");
  }
}
```

180.   Since boxes can be inside of boxes, *show_node_list* is inherently recursive, up to a given maximum number of levels. The history of nesting is indicated by the current string, which will be printed at the beginning of each line; the length of this string, namely *cur_length*, is the depth of nesting.

Recursive calls on *show_node_list* therefore use the following pattern:

#**define** *node_list_display*(A)
    { *append_char*('.'); *show_node_list*(A); *flush_char*;
    }   ▷ *str_room* need not be checked; see *show_box* below ◁

181.   A global variable called *depth_threshold* is used to record the maximum depth of nesting for which *show_node_list* will show information. If we have *depth_threshold* ≡ 0, for example, only the top level information will be given and no sublists will be traversed. Another global variable, called *breadth_max*, tells the maximum number of items to show at each level; *breadth_max* had better be positive, or you won't see anything.

⟨ Global variables 13 ⟩ +≡
  static int *depth_threshold*;   ▷ maximum nesting depth in box displays ◁
  static int *breadth_max*;   ▷ maximum number of items shown at the same list level ◁

182.   Now we are ready for *show_node_list* itself. This procedure has been written to be "extra robust" in the sense that it should not crash or get into a loop even if the data structures have been messed up by bugs in the rest of the program. You can safely call its parent routine *show_box*(*p*) for arbitrary values of *p* when you are debugging TeX. However, in the presence of bad data, the procedure may fetch a **memory_word** whose variant is different from the way it was stored; for example, it might try to read *mem*[*p*].*hh* when *mem*[*p*] contains a scaled integer, if *p* is a pointer that has been clobbered or chosen at random.

```
static void show_node_list(int p)      ▷ prints a node list symbolically ◁
{ int n;      ▷ the number of items already printed at this level ◁
  double g;       ▷ a glue ratio, as a floating point number ◁
  if (cur_length > depth_threshold) { if (p > null) print("␣[]");
          ▷ indicate that there's been some truncation ◁
    return;
  }
  n ← 0;
  while (p > mem_min) { print_ln(); print_current_string();      ▷ display the nesting history ◁
    if (p > mem_end)      ▷ pointer out of range ◁
    { print("Bad␣link,␣display␣aborted."); return;
    }
    incr(n);
    if (n > breadth_max)      ▷ time to stop ◁
    { print("etc."); return;
    }
    ⟨ Display node p 183 ⟩;
    p ← link(p);
  }
}
```

183.   ⟨ Display node *p* 183 ⟩ ≡
```
  if (is_char_node(p)) print_font_and_char(p);
  else
    switch (type(p)) {
    case hlist_node: case vlist_node: case unset_node: case unset_set_node: case unset_pack_node:
      ⟨ Display box p 184 ⟩ break;

     $print("box(")$; $print\_scaled(height(p))$; $print\_char('+')$; $print\_scaled(depth(p))$; $print(")x")$;
     $print\_scaled(width(p))$;
     if $(type(p) \equiv unset\_set\_node)$ $print("\sqcup set")$;
     else if $(type(p) \equiv unset\_pack\_node)$ $print("\sqcup pack")$;
     else if $(type(p) \equiv unset\_node)$ ⟨Display special fields of the unset node p 185⟩
     else { ⟨Display the value of $glue\_set(p)$ 186⟩;
        if $(shift\_amount(p) \neq 0)$ { $print(",\sqcup shifted\sqcup")$; $print\_scaled(shift\_amount(p))$;
        }
     }
     $node\_list\_display(list\_ptr(p))$;   ▷ recursive call ◁
   }

This code is used in section 183.

185.   ⟨Display special fields of the unset node p 185⟩ ≡
   { **if** $(span\_count(p) \neq min\_quarterword)$ { $print("\sqcup(")$; $print\_int(qo(span\_count(p)) + 1)$;
     $print("\sqcup columns)")$;
     }
     if $(glue\_stretch(p) \neq 0)$ { $print(",\sqcup stretch\sqcup")$; $print\_glue(glue\_stretch(p), glue\_order(p), 0)$;
     }
     if $(glue\_shrink(p) \neq 0)$ { $print(",\sqcup shrink\sqcup")$; $print\_glue(glue\_shrink(p), glue\_sign(p), 0)$;
     }
   }

This code is used in section 184.

186.   The code will have to change in this place if **glue_ratio** is a structured type instead of an ordinary **double**. Note that this routine should avoid arithmetic errors even if the $glue\_set$ field holds an arbitrary random value. The following code assumes that a properly formed nonzero **double** number has absolute value 2^{20} or more when it is regarded as an integer; this precaution was adequate to prevent floating point underflow on the author's computer.

⟨Display the value of $glue\_set(p)$ 186⟩ ≡
   $g \leftarrow unfix(glue\_set(p))$;
   if $((g \neq float\_constant(0)) \wedge (glue\_sign(p) \neq normal))$ { $print(",\sqcup glue\sqcup set\sqcup")$;
     if $(glue\_sign(p) \equiv shrinking)$ $print("-\sqcup")$;
     if $(abs(mem[p + glue\_offset].i) < °4000000)$ $print("?.?")$;
     else if $(abs(g) > float\_constant(20000))$ { **if** $(g > float\_constant(0))$ $print\_char('>')$;
       else $print("<\sqcup-")$;
       $print\_glue(20000 * unity, glue\_order(p), 0)$;
     }
     else $print\_glue(round(unity * g), glue\_order(p), 0)$;
   }

This code is used in section 184.

187.   ⟨Display rule p 187⟩ ≡
   { $print\_esc("rule(")$; $print\_rule\_dimen(height(p))$; $print\_char('+')$; $print\_rule\_dimen(depth(p))$;
     $print(")x")$; $print\_rule\_dimen(width(p))$;
   }

This code is used in section 183.

188. ⟨Display insertion p 188⟩ ≡

  { $print\_esc("insert")$; $print\_int(qo(subtype(p)))$; $print(";_{\sqcup}split(")$; $print\_spec(split\_top\_ptr(p), 0)$;
    $print\_char(',')$; $print\_scaled(depth(p))$; $print(");_{\sqcup}float_{\sqcup}cost_{\sqcup}")$; $print\_int(float\_cost(p))$;
    $node\_list\_display(ins\_ptr(p))$;   ▷ recursive call ◁
  }

This code is used in section 183.

189. ⟨Display glue p 189⟩ ≡

  if $(subtype(p) \geq a\_leaders)$ ⟨Display leaders p 190⟩
  else { $print\_esc("glue")$;
    if $(subtype(p) \neq normal)$ { $print\_char('(')$;
      if $(subtype(p) < cond\_math\_glue)$ $print\_skip\_param(subtype(p) - 1)$;
      else if $(subtype(p) \equiv cond\_math\_glue)$ $print\_esc("nonscript")$;
      else $print\_esc("mskip")$;
      $print\_char(')')$;
    }
    if $(subtype(p) \neq cond\_math\_glue)$ { $print\_char('_{\sqcup}')$;

    }
  }

This code is used in section 183.

193. ⟨Display ligature p 193⟩ ≡
  { $print\_font\_and\_char(lig\_char(p))$; $print("\_\sqcup(\text{ligature}\_\sqcup")$;
    if $(subtype(p) > 1)$ $print\_char('|')$;
    $font\_in\_short\_display \leftarrow font(lig\_char(p))$; $short\_display(lig\_ptr(p))$;
    if $(odd(subtype(p)))$ $print\_char('|')$;
    $print\_char(')')$;
  }

This code is used in section 183.

194. ⟨Display penalty p 194⟩ ≡
  { $print\_esc("\text{penalty}\_\sqcup")$; $print\_int(penalty(p))$;
  }

This code is used in section 183.

195. The *post_break* list of a discretionary node is indicated by a prefixed '|' instead of the '.' before the *pre_break* list.

⟨Display discretionary p 195⟩ ≡
  { $print\_esc("\text{discretionary}")$;
    if $(replace\_count(p) > 0)$ { $print("\_\sqcup\text{replacing}\_\sqcup")$; $print\_int(replace\_count(p))$;
    }
    $node\_list\_display(pre\_break(p))$;   ▷ recursive call ◁
    $append\_char('|')$; $show\_node\_list(post\_break(p))$; $flush\_char$;   ▷ recursive call ◁
  }

This code is used in section 183.

196. ⟨Display mark p 196⟩ ≡
  { $print\_esc("\text{mark}")$;
    if $(mark\_class(p) \neq 0)$ { $print\_char('s')$; $print\_int(mark\_class(p))$;
    }
    $print\_mark(mark\_ptr(p))$;
  }

This code is used in section 183.

197. ⟨Display adjustment p 197⟩ ≡
  { $print\_esc("\text{vadjust}")$; $node\_list\_display(adjust\_ptr(p))$;   ▷ recursive call ◁
  }

This code is used in section 183.

198. The recursive machinery is started by calling *show_box*.

  static void $show\_box(\textbf{pointer } p)$
  { ⟨Assign the values $depth\_threshold$: $\leftarrow show\_box\_depth$ and $breadth\_max$: $\leftarrow show\_box\_breadth$ 236⟩;
    if $(breadth\_max \leq 0)$ $breadth\_max \leftarrow 5$;
    if $(pool\_ptr + depth\_threshold \geq pool\_size)$ $depth\_threshold \leftarrow pool\_size - pool\_ptr - 1$;
        ▷ now there's enough room for prefix string ◁
    $show\_node\_list(p)$;   ▷ the show starts at p ◁
    $print\_ln()$;
  }

199.   Destroying boxes.   When we are done with a node list, we are obliged to return it to free storage, including all of its sublists. The recursive procedure *flush_node_list* does this for us.

200.   First, however, we shall consider two non-recursive procedures that do simpler tasks. The first of these, *delete_token_ref*, is called when a pointer to a token list's reference count is being removed. This means that the token list should disappear if the reference count was *null*, otherwise the count should be decreased by one.

#**define** *token_ref_count*(*A*)   *info*(*A*)   ▷ reference count preceding a token list ◁

  static void *delete_token_ref*(**pointer** *p*)
        ▷ *p* points to the reference count of a token list that is losing one reference ◁
  { **if** (*token_ref_count*(*p*) ≡ *null*) *flush_list*(*p*);
    else *decr*(*token_ref_count*(*p*));
  }

201.   Similarly, *delete_glue_ref* is called when a pointer to a glue specification is being withdrawn.

#**define** *fast_delete_glue_ref*(*A*)
        { **if** (*glue_ref_count*(*A*) ≡ *null*) *free_node*(*A*, *glue_spec_size*);
          else *decr*(*glue_ref_count*(*A*));
        }

  static void *delete_glue_ref*(**pointer** *p*)   ▷ *p* points to a glue specification ◁
  fast_delete_glue_ref(*p*)

  static void *delete_xdimen_ref*(**pointer** *p*)   ▷ *p* points to a xdimen specification ◁
  { **if** (*p* ≡ *null*) **return**;
    if (*xdimen_ref_count*(*p*) ≡ *null*) *free_node*(*p*, *xdimen_node_size*);
    else *decr*(*xdimen_ref_count*(*p*));
  }

202. Now we are ready to delete any node list, recursively. In practice, the nodes deleted are usually charnodes (about 2/3 of the time), and they are glue nodes in about half of the remaining cases.

```
static void flush_node_list(pointer p)      ▷erase list of nodes starting at p◁
{       ▷go here when node p has been freed◁
  pointer q;       ▷successor to node p◁
  while (p ≠ null) { q ← link(p);
    if (is_char_node(p)) free_avail(p)
    else { switch (type(p)) {
      case hlist_node: case vlist_node: case unset_node: case unset_set_node: case unset_pack_node:
        { flush_node_list(list_ptr(p)); free_node(p, box_node_size); goto done;
        }
      case rule_node:
        { free_node(p, rule_node_size); goto done;
        }
      case ins_node:
        { flush_node_list(ins_ptr(p)); delete_glue_ref(split_top_ptr(p)); free_node(p, ins_node_size);
          goto done;
        }
      case whatsit_node: ⟨Wipe out the whatsit node p and goto done 1359⟩
      case glue_node:
        { fast_delete_glue_ref(glue_ptr(p));
          if (leader_ptr(p) ≠ null) flush_node_list(leader_ptr(p));
        } break;
      case kern_node: case math_node: case penalty_node: do_nothing; break;
      case ligature_node: flush_node_list(lig_ptr(p)); break;
      case mark_node: delete_token_ref(mark_ptr(p)); break;
      case disc_node:
        { flush_node_list(pre_break(p)); flush_node_list(post_break(p));
        } break;
      case adjust_node: flush_node_list(adjust_ptr(p)); break;
      ⟨Cases of flush_node_list that arise in mlists only 698⟩
      default: confusion("flushing");
      }
      free_node(p, small_node_size);
    done: ;
    }
    p ← q;
  }
}
```

203.   Copying boxes.   Another recursive operation that acts on boxes is sometimes needed: The procedure *copy_node_list* returns a pointer to another node list that has the same structure and meaning as the original. Note that since glue specifications and token lists have reference counts, we need not make copies of them. Reference counts can never get too large to fit in a halfword, since each pointer to a node is in a different memory address, and the total number of memory addresses fits in a halfword.

(Well, there actually are also references from outside *mem*; if the *save_stack* is made arbitrarily large, it would theoretically be possible to break TeX by overflowing a reference count. But who would want to do that?)

#**define** *add_token_ref*(A) *incr*(*token_ref_count*(A))   ▷ new reference to a token list ◁
#**define** *add_glue_ref*(A) *incr*(*glue_ref_count*(A))   ▷ new reference to a glue spec ◁
#**define** *add_xdimen_ref*(A) **if** (A ≠ *null*) *incr*(*xdimen_ref_count*(A))   ▷ new reference to an xdimen ◁

204.   The copying procedure copies words en masse without bothering to look at their individual fields. If the node format changes—for example, if the size is altered, or if some link field is moved to another relative position—then this code may need to be changed too.

> **static pointer** *copy_node_list*(**pointer** p)
>   ▷ makes a duplicate of the node list that starts at p and returns a pointer to the new list ◁
> { **pointer** h;   ▷ temporary head of copied list ◁
>   **pointer** q;   ▷ previous position in new list ◁
>   **pointer** r;   ▷ current node being fabricated for new list ◁
>   **int** *words*;   ▷ number of words remaining to be copied ◁
>
>   h ← *get_avail*( ); q ← h;
>   **while** (p ≠ *null*) { ⟨ Make a copy of node p in node r 205 ⟩;
>   *link*(q) ← r; q ← r; p ← *link*(p);
>   }
>   *link*(q) ← *null*; q ← *link*(h); *free_avail*(h); **return** q;
> }

205.   ⟨ Make a copy of node p in node r 205 ⟩ ≡
  words ← 1;   ▷ this setting occurs in more branches than any other ◁
  if (*is_char_node*(p)) r ← *get_avail*( );
  else ⟨ Case statement to copy different types and set *words* to the number of initial words not yet

default: *confusion*("copying");

　}

This code is used in section 205.

207.   The command codes.   Before we can go any further, we need to define symbolic names for the internal code numbers that represent the various commands obeyed by TEX. These codes are somewhat arbitrary, but not completely so. For example, the command codes for character types are fixed by the language, since a user says, e.g., '\catcode `\$ = 3' to make $ a math delimiter, and the command code *math_shift* is equal to 3. Some other codes have been made adjacent so that **case** statements in the program need not consider cases that are widely spaced, or so that **case** statements can be replaced by **if** statements.

At any rate, here is the list, for future reference. First come the "catcode" commands, several of which share their numeric codes with ordinary commands when the catcode cannot emerge from TEX's scanning routine.

#**define** *escape*   0   ▷ escape delimiter (called \ in *The TEXbook*) ◁
#**define** *relax*   0   ▷ do nothing (\relax) ◁
#**define** *left_brace*   1   ▷ beginning of a group ({) ◁
#**define** *right_brace*   2   ▷ ending of a group (}) ◁
#**define** *math_shift*   3   ▷ mathematics shift character ($) ◁
#**define** *tab_mark*   4   ▷ alignment delimiter (&, \span) ◁
#**define** *car_ret*   5   ▷ end of line (*carriage_return*, \cr, \crcr) ◁
#**define** *out_param*   5   ▷ output a macro parameter ◁
#**define** *mac_param*   6   ▷ macro parameter symbol (#) ◁
#**define** *sup_mark*   7   ▷ superscript (^) ◁
#**define** *sub_mark*   8   ▷ subscript (_) ◁
#**define** *ignore*   9   ▷ characters to ignore (^^@) ◁
#**define** *endv*   9   ▷ end of $\langle v_j \rangle$ list in alignment template ◁
#**define** *spacer*   10   ▷ characters equivalent to blank space (␣) ◁
#**define** *letter*   11   ▷ characters regarded as letters (A..Z, a..z) ◁
#**define** *other_char*   12   ▷ none of the special character types ◁
#**define** *active_char*   13   ▷ characters that invoke macros (~) ◁
#**define** *par_end*   13   ▷ end of paragraph (\par) ◁
#**define** *match*   13   ▷ match a macro parameter ◁
#**define** *comment*   14   ▷ characters that introduce comments (%) ◁
#**define** *end_match*   14   ▷ end of parameters to macro ◁
#**define** *stop*   14   ▷ end of job (\end, \dump) ◁
#**define** *invalid_char*   15   ▷ characters that shouldn't appear (^^?) ◁
#**define** *delim_num*   15   ▷ specify delimiter numerically (\delimiter) ◁
#**define** *max_char_code*   15   ▷ largest catcode for individual characters ◁

208.   Next are the ordinary run-of-the-mill command codes. Codes that are *min_internal* or more represent internal quantities that might be expanded by '`\the`'.

#**define** *char_num* 16   ▷ character specified numerically (`\char`) ◁
#**define** *math_char_num* 17   ▷ explicit math code (`\mathchar`) ◁
#**define** *mark* 18   ▷ mark definition (`\mark`) ◁
#**define** *xray* 19   ▷ peek inside of TEX (`\show`, `\showbox`, etc.) ◁
#**define** *make_box* 20   ▷ make a box (`\box`, `\copy`, `\hbox`, etc.) ◁
#**define** *hmove* 21   ▷ horizontal motion (`\moveleft`, `\moveright`) ◁
#**define** *vmove* 22   ▷ vertical motion (`\raise`, `\lower`) ◁
#**define** *un_hbox* 23   ▷ unglue a box (`\unhbox`, `\unhcopy`) ◁
#**define** *un_vbox* 24   ▷ unglue a box (`\unvbox`, `\unvcopy`) ◁
              ▷ (or `\pagediscards`, `\splitdiscards`) ◁
#**define** *remove_item* 25   ▷ nullify last item (`\unpenalty`, `\unkern`, `\unskip`) ◁
#**define** *hskip* 26   ▷ horizontal glue (`\hskip`, `\hfil`, etc.) ◁
#**define** *vskip* 27   ▷ vertical glue (`\vskip`, `\vfil`, etc.) ◁
#**define** *mskip* 28   ▷ math glue (`\mskip`) ◁
#**define** *kern* 29   ▷ fixed space (`\kern`) ◁
#**define** *mkern* 30   ▷ math kern (`\mkern`) ◁
#**define** *leader_ship* 31   ▷ use a box (`\shipout`, `\leaders`, etc.) ◁
#**define** *halign* 32   ▷ horizontal table alignment (`\halign`) ◁
#**define** *valign* 33   ▷ vertical table alignment (`\valign`) ◁
#**define** *no_align* 34   ▷ temporary escape from alignment (`\noalign`) ◁
#**define** *vrule* 35   ▷ vertical rule (`\vrule`) ◁
#**define** *hrule* 36   ▷ horizontal rule (`\hrule`) ◁
#**define** *insert* 37   ▷ vlist inserted in box (`\insert`) ◁
#**define** *vadjust* 38   ▷ vlist inserted in enclosing paragraph (`\vadjust`) ◁
#**define** *ignore_spaces* 39   ▷ gobble *spacer* tokens (`\ignorespaces`) ◁
#**define** *after_assignment* 40   ▷ save till assignment is done (`\afterassignment`) ◁
#**define** *after_group* 41   ▷ save till group is done (`\aftergroup`) ◁
#**define** *break_penalty* 42   ▷ additional badness (`\penalty`) ◁
#**define** *start_par* 43   ▷ begin paragraph (`\indent`, `\noindent`) ◁
#**define** *ital_corr* 44   ▷ italic correction (`\/`) ◁
#**define** *accent* 45   ▷ attach accent in text (`\accent`) ◁
#**define** *math_accent* 46   ▷ attach accent in math (`\mathaccent`) ◁
#**define** *discretionary* 47   ▷ discretionary texts (`\-`, `\discretionary`) ◁
#**define** *eq_no* 48   ▷ equation number (`\eqno`, `\leqno`) ◁
#**define** *left_right* 49   ▷ variable delimiter (`\left`, `\right`) ◁   ▷ (or `\middle`) ◁
#**define** *math_comp* 50   ▷ component of formula (`\mathbin`, etc.) ◁
#**define** *limit_switch* 51   ▷ diddle limit conventions (`\displaylimits`, etc.) ◁
#**define** *above* 52   ▷ generalized fraction (`\above`, `\atop`, etc.) ◁
#**define** *math_style* 53   ▷ style specification (`\displaystyle`, etc.) ◁
#**define** *math_choice* 54   ▷ choice specification (`\mathchoice`) ◁
#**define** *non_script* 55   ▷ conditional math glue (`\nonscript`) ◁
#**define** *vcenter* 56   ▷ vertically center a vbox (`\vcenter`) ◁
#**define** *case_shift* 57   ▷ force specific case (`\lowercase`, `\uppercase`) ◁
#**define** *message* 58   ▷ send to user (`\message`, `\errmessage`) ◁
#**define** *extension* 59   ▷ extensions to TEX (`\write`, `\special`, etc.) ◁
#**define** *in_stream* 60   ▷ files for reading (`\openin`, `\closein`) ◁
#**define** *begin_group* 61   ▷ begin local grouping (`\begingroup`) ◁
#**define** *end_group* 62   ▷ end local grouping (`\endgroup`) ◁
#**define** *omit* 63   ▷ omit alignment template (`\omit`) ◁
#**define** *ex_space* 64   ▷ explicit space (`\␣`) ◁

#**define** *no_boundary* 65   ▷ suppress boundary ligatures (\noboundary) ◁
#**define** *radical* 66   ▷ square root and similar signs (\radical) ◁
#**define** *end_cs_name* 67   ▷ end control sequence (\endcsname) ◁
#**define** *min_internal* 68   ▷ the smallest code that can follow \the ◁
#**define** *char_given* 68   ▷ character code defined by \chardef ◁
#**define** *math_given* 69   ▷ math code defined by \mathchardef ◁
#**define** *last_item* 70   ▷ most recent item (\lastpenalty, \lastkern, \lastskip) ◁
#**define** *max_non_prefixed_command* 70   ▷ largest command code that can't be \global ◁

209.   The next codes are special; they all relate to mode-independent assignment of values to TEX's internal registers or tables. Codes that are *max_internal* or less represent internal quantities that might be expanded by '\the'.

#**define** *toks_register* 71   ▷ token list register (\toks) ◁
#**define** *assign_toks* 72   ▷ special token list (\output, \everypar, etc.) ◁
#**define** *assign_int* 73   ▷ user-defined integer (\tolerance, \day, etc.) ◁
#**define** *assign_dimen* 74   ▷ user-defined length (\hsize, etc.) ◁
#**define** *assign_glue* 75   ▷ user-defined glue (\baselineskip, etc.) ◁
#**define** *assign_mu_glue* 76   ▷ user-defined muglue (\thinmuskip, etc.) ◁
#**define** *assign_font_dimen* 77   ▷ user-defined font dimension (\fontdimen) ◁
#**define** *assign_font_int* 78   ▷ user-defined font integer (\hyphenchar, \skewchar) ◁
#**define** *set_aux* 79   ▷ specify state info (\spacefactor, \prevdepth) ◁
#**define** *set_prev_graf* 80   ▷ specify state info (\prevgraf) ◁
#**define** *set_page_dimen* 81   ▷ specify state info (\pagegoal, etc.) ◁
#**define** *set_page_int* 82   ▷ specify state info (\deadcycles, \insertpenalties) ◁
          ▷ (or \interactionmode) ◁
#**define** *set_box_dimen* 83   ▷ change dimension of box (\wd, \ht, \dp) ◁
#**define** *set_shape* 84   ▷ specify fancy paragraph shape (\parshape) ◁
          ▷ (or \interlinepenalties, etc.) ◁
#**define** *def_code* 85   ▷ define a character code (\catcode, etc.) ◁
#**define** *def_family* 86   ▷ declare math fonts (\textfont, etc.) ◁
#**define** *set_font* 87   ▷ set current font (font identifiers) ◁
#**define** *def_font* 88   ▷ define a font file (\font) ◁
#**define** *internal_register* 89   ▷ internal register (\count, \dimen, etc.) ◁
#**define** *max_internal* 89   ▷ the largest code that can follow \the ◁
#**define** *advance* 90   ▷ advance a register or parameter (\advance) ◁
#**define** *multiply* 91   ▷ multiply a register or parameter (\multiply) ◁
#**define** *divide* 92   ▷ divide a register or parameter (\divide) ◁
#**define** *prefix* 93   ▷ qualify a definition (\global, \long, \outer) ◁   ▷ (or \protected) ◁
#**define** *let* 94   ▷ assign a command code (\let, \futurelet) ◁
#**define** *shorthand_def* 95   ▷ code definition (\chardef, \countdef, etc.) ◁
#**define** *read_to_cs* 96   ▷ read into a control sequence (\read) ◁   ▷ (or \readline) ◁
#**define** *def* 97   ▷ macro definition (\def, \gdef, \xdef, \edef) ◁
#**define** *set_box* 98   ▷ set a box (\setbox) ◁
#**define** *hyph_data* 99   ▷ hyphenation data (\hyphenation, \patterns) ◁
#**define** *set_interaction* 100   ▷ define level of interaction (\batchmode, etc.) ◁
#**define** *max_command* 100   ▷ the largest command code seen at *big_switch* ◁

210.   The remaining command codes are extra special, since they cannot get through TEX's scanner to the main control routine. They have been given values higher than $max\_command$ so that their special nature is easily discernible. The "expandable" commands come first.

#define $undefined\_cs$ $(max\_command + 1)$ ▷ initial state of most eq_type fields ◁

#define $expand\_after$ $(max\_command + 2)$ ▷ special expansion (\expandafter) ◁

#define no_expand $(max\_command + 3)$ ▷ special nonexpansion (\noexpand) ◁

#define $input$ $(max\_command + 4)$ ▷ input a source file (\input, \endinput) ◁
                ▷ (or \scantokens) ◁

#define if_test $(max\_command + 5)$ ▷ conditional text (\if, \ifcase, etc.) ◁

#define fi_or_else $(max\_command + 6)$ ▷ delimiters for conditionals (\else, etc.) ◁

#define cs_name $(max\_command + 7)$ ▷ make a control sequence from tokens (\csname) ◁

#define $convert$ $(max\_command + 8)$ ▷ convert to text (\number, \string, etc.) ◁

#define the $(max\_command + 9)$ ▷ expand an internal quantity (\the) ◁
                ▷ (or \unexpanded, \detokenize) ◁

#define top_bot_mark $(max\_command + 10)$ ▷ inserted mark (\topmark, etc.) ◁

#define $call$ $(max\_command + 11)$ ▷ non-long, non-outer control sequence ◁

#define $long\_call$ $(max\_command + 12)$ ▷ long, non-outer control sequence ◁

#define $outer\_call$ $(max\_command + 13)$ ▷ non-long, outer control sequence ◁

#define $long\_outer\_call$ $(max\_command + 14)$ ▷ long, outer control sequence ◁

#define $end\_template$ $(max\_command + 15)$ ▷ end of an alignment template ◁

#define $dont\_expand$ $(max\_command + 16)$ ▷ the following token was marked by \noexpand ◁

#define $glue\_ref$ $(max\_command + 17)$ ▷ the equivalent points to a glue specification ◁

#define $shape\_ref$ $(max\_command + 18)$ ▷ the equivalent points to a parshape specification ◁

#define box_ref $(max\_command + 19)$ ▷ the equivalent points to a box node, or is $null$ ◁

#define $data$ $(max\_command + 20)$ ▷ the equivalent is simply a halfword number ◁

211.   The semantic nest.   TEX is typically in the midst of building many lists at once. For example, when a math formula is being processed, TEX is in math mode and working on an mlist; this formula has temporarily interrupted TEX from being in horizontal mode and building the hlist of a paragraph; and this paragraph has temporarily interrupted TEX from being in vertical mode and building the vlist for the next page of a document. Similarly, when a \vbox occurs inside of an \hbox, TEX is temporarily interrupted from working in restricted horizontal mode, and it enters internal vertical mode. The "semantic nest" is a stack that keeps track of what lists and modes are currently suspended.

   At each level of processing we are in one of six modes:

vmode stands for vertical mode (the page builder);
hmode stands for horizontal mode (the paragraph builder);
mmode stands for displayed formula mode;
$-vmode$ stands for internal vertical mode (e.g., in a \vbox);
$-hmode$ stands for restricted horizontal mode (e.g., in an \hbox);
$-mmode$ stands for math formula mode (not displayed).

The mode is temporarily set to zero while processing \write texts.

   Numeric values are assigned to *vmode*, *hmode*, and *mmode* so that TEX's "big semantic switch" can select the appropriate thing to do by computing the value $abs(mode) + cur\_cmd$, where *mode* is the current mode and cur_cmd is the current command code.

#**define** *vmode*   1   ▷ vertical mode ◁
#**define** *hmode* $(vmode + max\_command + 1)$ ▷ horizontal mode ◁
#**define** *mmode* $(hmode + max\_command + 1)$ ▷ math mode ◁

   static void *print_mode*(**int** *m*)   ▷ prints the mode represented by m ◁
   { **if** $(m > 0)$
      switch $(m/(max\_command + 1))$ {
      case 0: *print*("vertical"); **break**;
      case 1: *print*("horizontal"); **break**;
      case 2: *print*("display␣math");
      }
    else if $(m \equiv 0)$ *print*("no");
    else
      switch $((-m)/(max\_command + 1))$ {
      case 0: *print*("internal␣vertical"); **break**;
      case 1: *print*("restricted␣horizontal"); **break**;
      case 2: *print*("math");
      }
    print("␣mode");
   }

212.   The state of affairs at any semantic level can be represented by five values:

mode is the number representing the semantic mode, as just explained.

head is a **pointer** to a list head for the list being built; *link*(*head*) therefore points to the first element of the list, or to *null* if the list is empty.

tail is a **pointer** to the final node of the list being built; thus, *tail* ≡ *head* if and only if the list is empty.

prev_graf is the number of lines of the current paragraph that have already been put into the present vertical list.

aux is an auxiliary **memory_word** that gives further information that is needed to characterize the situation.

In vertical mode, *aux* is also known as *prev_depth*; it is the scaled value representing the depth of the previous box, for use in baseline calculations, or it is ≤ −1000pt if the next box on the vertical list is to be exempt from baseline calculations. In horizontal mode, *aux* is also known as *space_factor* and *clang*; it holds the current space factor used in spacing calculations, and the current language used for hyphenation. (The value of *clang* is undefined in restricted horizontal mode.) In math mode, *aux* is also known as *incompleat_noad*; if not *null*, it points to a record that represents the numerator of a generalized fraction for which the denominator is currently being formed in the current list.

There is also a sixth quantity, *mode_line*, which correlates the semantic nest with the user's input; *mode_line* contains the source line number at which the current level of nesting was entered. The negative of this line number is the *mode_line* at the level of the user's output routine.

A seventh quantity, *eTeX_aux*, is used by the extended features ε-TEX. In vertical modes it is known as *LR_save* and holds the LR stack when a paragraph is interrupted by a displayed formula. In display math mode it is known as *LR_box* and holds a pointer to a prototype box for the display. In math mode it is known as *delim_ptr* and points to the most recent *left_noad* or *middle_noad* of a *math_left_group*.

In horizontal mode, the *prev_graf* field is used for initial language data.

The semantic nest is an array called *nest* that holds the *mode*, *head*, *tail*, *prev_graf*, *aux*, and *mode_line* values for all semantic levels below the currently active one. Information about the currently active level is kept in the global quantities *mode*, *head*, *tail*, *prev_graf*, *aux*, and *mode_line*, which live in a Pascal record that is ready to be pushed onto *nest* if necessary.

#**define** *ignore_depth* (−1000 ∗ *unity*)   ▷ *prev_depth* value that is ignored ◁
#**define** *unknown_depth* (−2000 ∗ *unity*)   ▷ *prev_depth* value that is unknown ◁

⟨ Types in the outer block 18 ⟩ +≡
    typedef struct {
      int16_t *mode_field*; **pointer** *head_field*, *tail_field*;
      pointer *eTeX_aux_field*;
      int *pg_field*, *ml_field*; **memory_word** *aux_field*;
    } **list_state_record**;

213.   #**define** *mode*   *cur_list.mode_field*   ▷ current mode ◁

#**define** *head*   *cur_list.head_field*   ▷ header node of current list ◁

#**define** *tail*   *cur_list.tail_field*   ▷ final node on current list ◁

#**define** *eTeX_aux*   *cur_list.eTeX_aux_field*   ▷ auxiliary data for ε-TeX ◁

#**define** *LR_save*   *eTeX_aux*   ▷ LR stack when a paragraph is interrupted ◁

#**define** *LR_box*   *eTeX_aux*   ▷ prototype box for display ◁

#**define** *delim_ptr*   *eTeX_aux*   ▷ most recent left or right noad of a math left group ◁

#**define** *prev_graf*   *cur_list.pg_field*   ▷ number of paragraph lines accumulated ◁

#**define** *aux*   *cur_list.aux_field*   ▷ auxiliary data about the current list ◁

#**define** *prev_depth*   *aux.sc*   ▷ the name of *aux* in vertical mode ◁

#**define** *space_factor*   *aux.hh.lh*   ▷ part of *aux* in horizontal mode ◁

#**define** *clang*   *aux.hh.rh*   ▷ the other part of *aux* in horizontal mode ◁

#**define** *incompleat_noad*   *aux.i*   ▷ the name of *aux* in math mode ◁

#**define** *mode_line*   *cur_list.ml_field*   ▷ source file line number at beginning of list ◁

⟨ Global variables 13 ⟩ +≡

  static list_state_record *nest*[*nest_size* + 1];

  static int *nest_ptr*;   ▷ first unused location of *nest* ◁

  static int *max_nest_stack*;   ▷ maximum of *nest_ptr* when pushing ◁

  static list_state_record *cur_list*;   ▷ the "top" semantic state ◁

  static int *shown_mode*;   ▷ most recent mode shown by \tracingcommands ◁

214.   Here is a common way to make the current list grow:

#**define** *tail_append*(*A*)

    { *link*(*tail*) ← *A*; *tail* ← *link*(*tail*);

    }

215.   We will see later that the vertical list at the bottom semantic level is split into two parts; the "current page" runs from *page_head* to *page_tail*, and the "contribution list" runs from *contrib_head* to *tail* of semantic level zero. The idea is that contributions are first formed in vertical mode, then "contributed" to the current page (during which time the page-breaking decisions are made). For now, we don't need to know any more details about the page-building process.

⟨ Set initial values of key variables 21 ⟩ +≡

  nest_ptr ← 0; *max_nest_stack* ← 0; *mode* ← *vmode*; *head* ← *contrib_head*; *tail* ← *contrib_head*;

  eTeX_aux ← *null*; *prev_depth* ← *ignore_depth*; *mode_line* ← 0; *prev_graf* ← 0; *shown_mode* ← 0;

  ⟨ Start a new current page 991 ⟩;

216.   When TeX's work on one level is interrupted, the state is saved by calling *push_nest*. This routine changes *head* and *tail* so that a new (empty) list is begun; it does not change *mode* or *aux*.

  static void *push_nest*(**void**)   ▷ enter a new semantic level, save the old ◁

  { **if** (*nest_ptr* > *max_nest_stack*) { *max_nest_stack* ← *nest_ptr*;

    if (*nest_ptr* ≡ *nest_size*) *overflow*("semantic␣nest␣size", *nest_size*);

  }

  nest[*nest_ptr*] ← *cur_list*;   ▷ stack the record ◁

  incr(*nest_ptr*); *head* ← *get_avail*( ); *tail* ← *head*; *prev_graf* ← 0; *mode_line* ← *line*;

  eTeX_aux ← *null*;

  }

217.   Conversely, when TEX is finished on the current level, the former state is restored by calling *pop_nest*. This routine will never be called at the lowest semantic level, nor will it be called unless *head* is a node that should be returned to free memory.

> **static void** *pop_nest*(**void**)   ▷ leave a semantic level, re-enter the old ◁
> { *free_avail*(*head*); *decr*(*nest_ptr*); *cur_list* ← *nest*[*nest_ptr*];
> }

218.   Here is a procedure that displays what TEX is working on, at all levels.

This code is used in section 218.

220.   The table of equivalents.   Now that we have studied the data structures for TeX's semantic routines, we ought to consider the data structures used by its syntactic routines. In other words, our next concern will be the tables that TeX looks at when it is scanning what the user has written.

The biggest and most important such table is called *eqtb*. It holds the current "equivalents" of things; i.e., it explains what things mean or what their current values are, for all quantities that are subject to the nesting structure provided by TeX's grouping mechanism. There are six parts to *eqtb*:

1) *eqtb*[*active_base* .. (*hash_base* − 1)] holds the current equivalents of single-character control sequences.

2) *eqtb*[*hash_base* .. (*glue_base* − 1)] holds the current equivalents of multiletter control sequences.

3) *eqtb*[*glue_base* .. (*local_base* − 1)] holds the current equivalents of glue parameters like the current baselineskip.

4) *eqtb*[*local_base* .. (*int_base* − 1)] holds the current equivalents of local halfword quantities like the current box registers, the current "catcodes," the current font, and a pointer to the current paragraph shape.

5) *eqtb*[*int_base* .. (*dimen_base* − 1)] holds the current equivalents of fullword integer parameters like the current hyphenation penalty.

6) *eqtb*[*dimen_base* .. *eqtb_size*] holds the current equivalents of fullword dimension parameters like the current hsize or amount of hanging indentation.

Note that, for example, the current amount of baselineskip glue is determined by the setting of a particular location in region 3 of *eqtb*, while the current meaning of the control sequence '`\baselineskip`' (which might have been changed by `\def` or `\let`) appears in region 2.

221.   Each entry in *eqtb* is a **memory_word**. Most of these words are of type **two_halves**, and subdivided into three fields:

1) The *eq_level* (a quarterword) is the level of grouping at which this equivalent was defined. If the level is *level_zero*, the equivalent has never been defined; *level_one* refers to the outer level (outside of all groups), and this level is also used for global definitions that never go away. Higher levels are for equivalents that will disappear at the end of their group.

2) The *eq_type* (another quarterword) specifies what kind of entry this is. There are many types, since each TeX primitive like `\hbox`, `\def`, etc., has its own special code. The list of command codes above includes all possible settings of the *eq_type* field.

3) The *equiv* (a halfword) is the current equivalent value. This may be a font number, a pointer into *mem*, or a variety of other things.

#**define** *eq_level_field*(*A*)   *A.hh.b1*
#**define** *eq_type_field*(*A*)   *A.hh.b0*
#**define** *equiv_field*(*A*)   *A.hh.rh*
#**define** *eq_level*(*A*)   *eq_level_field*(*eqtb*[*A*])   ▷ level of definition ◁
#**define** *eq_type*(*A*)   *eq_type_field*(*eqtb*[*A*])   ▷ command code for equivalent ◁
#**define** *equiv*(*A*)   *equiv_field*(*eqtb*[*A*])   ▷ equivalent value ◁
#**define** *level_zero*   *min_quarterword*   ▷ level for undefined quantities ◁
#**define** *level_one*   (*level_zero* + 1)   ▷ outermost level for defined quantities ◁

222. Many locations in *eqtb* have symbolic names. The purpose of the next paragraphs is to define these names, and to set up the initial values of the equivalents.

In the first region we have 256 equivalents for "active characters" that act as control sequences, followed by 256 equivalents for single-character control sequences.

Then comes region 2, which corresponds to the hash table that we will define later. The maximum address in this region is used for a dummy control sequence that is perpetually undefined. There also are several locations for control sequences that are perpetually defined (since they are used in error recovery).

#**define** *active_base* 1   ▷ beginning of region 1, for active character equivalents ◁
#**define** *single_base* (*active_base* + 256)   ▷ equivalents of one-character control sequences ◁
#**define** *null_cs* (*single_base* + 256)   ▷ equivalent of \csname\endcsname ◁
#**define** *hash_base* (*null_cs* + 1)   ▷ beginning of region 2, for the hash table ◁
#**define** *frozen_control_sequence* (*hash_base* + *hash_size*)   ▷ for error recovery ◁
#**define** *frozen_protection* *frozen_control_sequence*   ▷ inaccessible but definable ◁
#**define** *frozen_cr* (*frozen_control_sequence* + 1)   ▷ permanent '\cr' ◁
#**define** *frozen_end_group* (*frozen_control_sequence* + 2)   ▷ permanent '\endgroup' ◁
#**define** *frozen_right* (*frozen_control_sequence* + 3)   ▷ permanent '\right' ◁
#**define** *frozen_fi* (*frozen_control_sequence* + 4)   ▷ permanent '\fi' ◁
#**define** *frozen_end_template* (*frozen_control_sequence* + 5)   ▷ permanent '\endtemplate' ◁
#**define** *frozen_endv* (*frozen_control_sequence* + 6)   ▷ second permanent '\endtemplate' ◁
#**define** *frozen_relax* (*frozen_control_sequence* + 7)   ▷ permanent '\relax' ◁
#**define** *end_write* (*frozen_control_sequence* + 8)   ▷ permanent '\endwrite' ◁
#**define** *frozen_dont_expand* (*frozen_control_sequence* + 9)   ▷ permanent '\notexpanded:' ◁
#**define** *frozen_primitive* (*frozen_control_sequence* + 10)   ▷ permanent '\primitive:' ◁
#**define** *frozen_null_font* (*frozen_control_sequence* + 11)   ▷ permanent '\nullfont' ◁
#**define** *font_id_base* (*frozen_null_font* − *font_base*)   ▷ begins table of 257 permanent font identifiers ◁
#**define** *undefined_control_sequence* (*frozen_null_font* + 257)   ▷ dummy location ◁
#**define** *glue_base* (*undefined_control_sequence* + 1)   ▷ beginning of region 3 ◁

⟨ Initialize table entries (done by INITEX only) 164 ⟩ +≡
   eq_type(*undefined_control_sequence*) ← *undefined_cs*; $equiv$(*undefined_control_sequence*) ← *null*;

    } **break**;

232.   We initialize most things to null or undefined values. An undefined font is represented by the internal code *font_base*.

However, the character code tables are given initial values based on the conventional interpretation of ASCII code. These initial values should not be changed when TeX is adapted for use with non-English languages; all changes to the initialization conventions should be made in format packages, not in TeX itself, so that global interchange of formats is possible.

236.   Region 5 of *eqtb* contains the integer parameters and registers defined here, as well as the *del_code* table. The latter table differs from the *cat_code .. math_code* tables that precede it, since delimiter codes are fullword integers while the other kinds of codes occupy at most a halfword. This is what makes region 5 different from region 4. We will store the *eq_level* information in an auxiliary array of quarterwords that will be defined later.

239. ⟨Cases of $print\_cmd\_chr$ for symbolic printing of primitives 227⟩ +≡
case $assign\_int$:
  if $(chr\_code < count\_base)$ $print\_param(chr\_code - int\_base)$;
  else { $print\_esc($"count"$)$; $print\_int(chr\_code - count\_base)$;
  } **break**;

240. The integer parameters should really be initialized by a macro package; the following initialization does the minimum to keep TℰX from complete failure.

⟨Initialize table entries (done by `INITEX` only) 164⟩ +≡
  for $(k \leftarrow int\_base$; $k \leq del\_code\_base - 1$; $k{+}{+})$ $eqtb[k].i \leftarrow 0$;
  $mag \leftarrow 1000$; $tolerance \leftarrow 10000$; $hang\_after \leftarrow 1$; $max\_dead\_cycles \leftarrow 25$; $escape\_char \leftarrow$ '$\backslash\backslash$';
  $end\_line\_char \leftarrow carriage\_return$;
  for $(k \leftarrow 0$; $k \leq 255$; $k{+}{+})$ $del\_code(k) \leftarrow -1$;
  $del\_code($'.'$) \leftarrow 0$;   ▷ this null delimiter is used in error recovery ◁

241. The following procedure, which is called just before TℰX initializes its input and output, establishes the initial values of the date and time. This does include too, for system integrators, the creation date and the reference moment for the timer—PR⊙TℰX extensions. If the system supports environment variables, if `FORCE_SOURCE_DATE` is set to 1 and `SOURCE_DATE_EPOCH` is set, the date related values: year, month, day and time, including creation date, will be taken relative from the value defined by `SOURCE_DATE_EPOCH`. TℰX Live calls tl_now to obtain the current time as a **tm** structure.

  static void $fix\_date\_and\_time($**void**$)$
  { **struct tm** $*t \leftarrow tl\_now()$;

    $time \leftarrow sys\_time \leftarrow t{\rightarrow}tm\_hour * 60 + t{\rightarrow}tm\_min$;   ▷ minutes since midnight ◁
    $day \leftarrow sys\_day \leftarrow t{\rightarrow}tm\_mday$;   ▷ day of the month ◁
    $month \leftarrow sys\_month \leftarrow t{\rightarrow}tm\_mon + 1$;   ▷ month of the year ◁

    $print\_char$(′)′);
  }
  }
This code is used in section 172.

256.   The hash table.   Control sequences are stored and retrieved by means of a fairly standard hash table algorithm called the method of "coalescing lists" (cf. Algorithm 6.4C in *The Art of Computer Programming*). Once a control sequence enters the table, it is never removed, because there are complicated situations involving \gdef where the removal of a control sequence at the end of a group would be a mistake preventable only by the introduction of a complicated reference-count mechanism.

The actual sequence of letters forming a control sequence identifier is stored in the *str_pool* array together with all the other strings. An auxiliary array *hash* consists of items with two halfword fields per word. The first of these, called *next*(p), points to the next identifier belonging to the same coalesced list as the identifier corresponding to p; and the other, called *text*(p), points to the *str_start* entry for p's identifier. If position p of the hash table is empty, we have $text(p) \equiv 0$; if position p is either empty or the end of a coalesced hash list, we have $next(p) \equiv 0$. An auxiliary pointer variable called *hash_used* is maintained in such a way that all locations $p \geq hash\_used$ are nonempty. The global variable *cs_count* tells how many multiletter control sequences have been defined, if statistics are being kept.

A global boolean variable called *no_new_control_sequence* is set to *true* during the time that new hash table entries are forbidden.

#**define** $next(A)$ $hash[A].lh$ ▷ link for coalesced lists ◁
#**define** $text(A)$ $hash[A].rh$ ▷ string number for control sequence name ◁
#**define** $hash\_is\_full$ $(hash\_used \equiv hash\_base)$ ▷ test if all positions are occupied ◁

    $text(p) \leftarrow make\_string()$; $pool\_ptr \leftarrow pool\_ptr + d$;

#ifdef STAT

    $incr(cs\_count)$;

#endif

  }

This code is used in section 259.

261.   The value of *hash_prime* should be roughly 85% of *hash_size*, and it should be a prime number. The theory of hashing tells us to expect fewer than two table probes, on the average, when the search is successful. [See J. S. Vitter, *Journal of the ACM* **30** (1983), 231–258.]

⟨ Compute the hash code h 261 ⟩ ≡
> $h \leftarrow buffer[j]$;
> **for** $(k \leftarrow j + 1;\ k \leq j + l - 1;\ k\!+\!+)$ { $h \leftarrow h + h + buffer[k]$;
> > **while** $(h \geq hash\_prime)\ h \leftarrow h - hash\_prime$;
> }

This code is used in section 259.

262.   Single-character control sequences do not need to be looked up in a hash table, since we can use the character code itself as a direct address. The procedure *print_cs* prints the name of a control sequence, given a pointer to its address in *eqtb*. A space is printed after the name unless it is a single nonletter or an active character. This procedure might be invoked with invalid data, so it is "extra robust." The individual characters must be printed one at a time using *print*, since they may be unprintable.

⟨ Basic printing procedures 56 ⟩ +≡
> **static void** *print_cs*(**int** *p*)   ▷ prints a purported control sequence ◁
> { **if** $(p < hash\_base)$ ▷ single character ◁
> > **if** $(p \geq single\_base)$
> > > **if** $(p \equiv null\_cs)$ { *print_esc*("csname"); *print_esc*("endcsname"); *print_char*('␣');
> > > }
> > > **else** { *printn_esc*$(p - single\_base)$;
> > > > **if** $(cat\_code(p - single\_base) \equiv letter)$ *print_char*('␣');
> > > }
> > **else if** $(p < active\_base)$ *print_esc*("IMPOSSIBLE.");
> > **else** *printn*$(p - active\_base)$;
> > **else if** $(p \geq undefined\_control\_sequence)$ *print_esc*("IMPOSSIBLE.");
> > **else if** $((text(p) < 0) \vee (text(p) \geq str\_ptr))$ *print_esc*("NONEXISTENT.");
> > **else** { **if** $(p \equiv frozen\_primitive)$ *print_esc*("primitive");
> > > *printn_esc*$(text(p))$; *print_char*('␣');
> > }
> }

263.   Here is a similar procedure; it avoids the error checks, and it never prints a space after the control sequence.

⟨ Basic printing procedures 56 ⟩ +≡
> **static void** *sprint_cs*(**pointer** *p*)   ▷ prints a control sequence ◁
> { **if** $(p < hash\_base)$

> > **else** { *print_esc*("csname"); *print_esc*("endcsname");
> > }
> **else** *printn_esc*$(text(p))$;
> }

264. We need to put TₑX's "primitive" control sequences into the hash table, together with their command code (which will be the *eq_type*) and an operand (which will be the *equiv*). The *primitive* procedure does this, in a way that no TₑX user can. The global value *cur_val* contains the new *eqtb* pointer after *primitive* has acted.

#ifdef INIT
  static void *primitive*(**char** *∗str*, **quarterword** *c*, **halfword** *o*)
  { **str_number** *s ← s_no*(*str*);

267.   We will deal with the other primitives later, at some point in the program where their *eq_type* and *equiv* values are more meaningful. For example, the primitives for math mode will be loaded when we consider the routines that deal with formulas. It is easy to find where each particular primitive was treated by looking in the index at the end; for example, the section where "radical" entered *eqtb* is listed under '\radical primitive'. (Primitives consisting of a single nonalphabetic character, like '\/', are listed under 'Single-character primitives'.)

Meanwhile, this is a convenient place to catch up on something we were unable to do before the hash table was defined:

⟨ Print the font identifier for *font*(*p*) 267 ⟩ ≡
  printn_esc(*font_id_text*(*font*(*p*)));

This code is used in sections 174 and 176.

268.   Saving and restoring equivalents.   The nested structure provided by '{ ... }' groups in TEX means that *eqtb* entries valid in outer groups should be saved and restored later if they are overridden inside the braces. When a new *eqtb* value is being assigned, the program therefore checks to see if the previous entry belongs to an outer level. In such a case, the old value is placed on the *save_stack* just before the new value enters *eqtb*. At the end of a grouping level, i.e., when the right brace is sensed, the *save_stack* is used to restore the outer values, and the inner ones are destroyed.

Entries on the *save_stack* are of type **memory_word**. The top item on this stack is *save_stack*[p], where $p \equiv save\_ptr - 1$; it contains three fields called *save_type*, *save_level*, and *save_index*, and it is interpreted in one of five ways:

1) If *save_type*(p) $\equiv$ *restore_old_value*, then *save_index*(p) is a location in *eqtb* whose current value should be destroyed at the end of the current group and replaced by *save_stack*[$p - 1$]. Furthermore if *save_index*(p) $\geq$ *int_base*, then *save_level*(p) should replace the corresponding entry in *xeq_level*.

2) If *save_type*(p) $\equiv$ *restore_zero*, then *save_index*(p) is a location in *eqtb* whose current value should be destroyed at the end of the current group, when it should be replaced by the value of *eqtb*[*undefined_control_sequence*].

3) If *save_type*(p) $\equiv$ *insert_token*, then *save_index*(p) is a token that should be inserted into TEX's input when the current group ends.

4) If *save_type*(p) $\equiv$ *level_boundary*, then *save_level*(p) is a code explaining what kind of group we were previously in, and *save_index*(p) points to the level boundary word at the bottom of the entries for that group. Furthermore, in extended ε-TEX mode, *save_stack*[$p-1$] contains the source line number at which the current level of grouping was entered.

5) If *save_type*(p) $\equiv$ *restore_sa*, then *sa_chain* points to a chain of sparse array entries to be restored at the end of the current group. Furthermore *save_index*(p) and *save_level*(p) should replace the values of *sa_chain* and *sa_level* respectively.

#**define** *save_type*(A)   *save_stack*[A].*hh.b0*   ▷ classifies a *save_stack* entry ◁

⟨ Declare ε-TEX procedures for tracing and input 284 ⟩

269.   Here are the group codes that are used to discriminate between different kinds of groups. They allow
TEX to decide what special actions, if any, should be performed when a group ends.

Some groups are not supposed to be ended by right braces. For example, the '`$`' that begins a math formula
causes a *math_shift_group* to be started, and this should be terminated by a matching '`$`'. Similarly, a group
that starts with `\left` should end with `\right`, and one that starts with `\begingroup` should end with
`\endgroup`.

⟨ Types in the outer block 18 ⟩ +≡
  typedef int8_t group_code;   ▷ *save_level* for a level boundary ◁

270.   The global variable *cur_group* keeps track of what sort of group we are currently in. Another global
variable, *cur_boundary*, points to the topmost *level_boundary* word. And *cur_level* is the current depth of
nesting. The routines are designed to preserve the condition that no entry in the *save_stack* or in *eqtb* ever
has a level greater than *cur_level*.

271.   ⟨ Global variables 13 ⟩ +≡
  static memory_word *save_stack*[*save_size* + 1];
  static memory_word *save_hfactor*[*save_size* + 1];
  static memory_word *save_vfactor*[*save_size* + 1];
  static int *save_ptr*;   ▷ first unused entry on *save_stack* ◁
  static int *max_save_stack*;   ▷ maximum usage of save stack ◁
  static quarterword *cur_level*;   ▷ current nesting level for groups ◁
  static group_code *cur_group*;   ▷ current group type ◁
  static int *cur_boundary*;   ▷ where the current level begins ◁

272.   At this time it might be a good idea for the reader to review the introduction to *eqtb* that was given above just before the long lists of parameter names. Recall that the "outer level" of the program is *level_one*, since undefined control sequences are assumed to be "defined" at *level_zero*.

⟨ Set initial values of key variables 21 ⟩ +≡
  save_ptr ← 0; *cur_level* ← *level_one*; *cur_group* ← *bottom_level*; *cur_boundary* ← 0;
  max_save_stack ← 0;

273.   The following macro is used to test if there is room for up to seven more entries on *save_stack*. By making a conservative test like this, we can get by with testing for overflow in only a few places.

#**define** *check_full_save_stack*
        if (*save_ptr* > *max_save_stack*) { *max_save_stack* ← *save_ptr*;
          if (*max_save_stack* > *save_size* − 7) *overflow*("save␣size", *save_size*);
        }

274.   Procedure *new_save_level* is called when a group begins. The argument is a group identification code like '*hbox_group*'. After calling this routine, it is safe to put five more entries on *save_stack*.

   In some cases integer-valued items are placed onto the *save_stack* just below a *level_boundary* word, because this is a convenient place to keep information that is supposed to "pop up" just when the group has finished. For example, when '\hbox to 100pt{...}' is being treated, the 100pt dimension is stored on *save_stack* just before *new_save_level* is called.

   We use the notation *saved*(*k*) to stand for an integer item that appears in location *save_ptr* + *k* of the save stack.

#**define** *saved*(*A*) *save_stack*[*save_ptr* + *A*].*i*
#**define** *saved_hfactor*(*A*) *save_hfactor*[*save_ptr* + *A*].*i*
#**define** *saved_vfactor*(*A*) *save_vfactor*[*save_ptr* + *A*].*i*

  static void *new_save_level*(**group_code** *c*)   ▷ begin a new level of grouping ◁
  { *check_full_save_stack*;
    if (*eTeX_ex*) { *saved*(0) ← *line*; *incr*(*save_ptr*);
    }
    save_type(*save_ptr*) ← *level_boundary*; *save_level*(*save_ptr*) ← *cur_group*;
    save_index(*save_ptr*) ← *cur_boundary*;
    if (*cur_level* ≡ *max_quarterword*)
      overflow("grouping␣levels", *max_quarterword* − *min_quarterword*);
          ▷ quit if (*cur_level* + 1) is too big to be stored in *eqtb* ◁
    cur_boundary ← *save_ptr*; *cur_group* ← *c*;
#**ifdef** STAT
    if (*tracing_groups* > 0) *group_trace*(*false*);
#**endif**
    incr(*cur_level*); *incr*(*save_ptr*);
  }

275.   Just before an entry of *eqtb* is changed, the following procedure should be called to update the other data structures properly. It is important to keep in mind that reference counts in *mem* include references from within *save_stack*, so these counts must be handled carefully.

> **static void** *eq_destroy*(**memory_word** *w*)   ▷ gets ready to forget *w* ◁
> { **pointer** *q*;   ▷ *equiv* field of *w* ◁
>
>   **switch** (*eq_type_field*(*w*)) {

>   ⟨ Cases for *eq_destroy* 1518 ⟩
>   **default**: *do_nothing*;
>   }
> }

276.   To save a value of *eqtb*[*p*] that was established at level *l*, we can use the following subroutine.

> **static void** *eq_save*(**pointer** *p*, **quarterword** *l*)   ▷ saves *eqtb*[*p*] ◁
> { *check_full_save_stack*;
>   **if** (*l* ≡ *level_zero*) *save_type*(*save_ptr*) ← *restore_zero*;
>   **else** { *save_stack*[*save_ptr*] ← *eqtb*[*p*];
>   **if** (*p* ≥ *dimen_base*) {
>   *save_hfactor*[*save_ptr*] ← *hfactor_eqtb*[*p*]; *save_vfactor*[*save_ptr*] ← *vfactor_eqtb*[*p*];
>   }
>   **else if** (*p* ≡ *par_shape_loc*) {
>   *save_hfactor*[*save_ptr*].*i* ← *par_shape_hfactor*; *save_vfactor*[*save_ptr*].*i* ← *par_shape_vfactor*;
>   }
>   *incr*(*save_ptr*); *save_type*(*save_ptr*) ← *restore_old_value*;
>   }
>   *save_level*(*save_ptr*) ← *l*; *save_index*(*save_ptr*) ← *p*; *incr*(*save_ptr*);
> }

277. The procedure *eq_define* defines an *eqtb* entry having specified *eq_type* and *equiv* fields, and saves the former value if appropriate. This procedure is used only for entries in the first four regions of *eqtb*, i.e., only for entries that have *eq_type* and *equiv* fields. After calling this routine, it is safe to put four more entries on *save_stack*, provided that there was room for four more entries before the call, since *eq_save* makes the necessary test.

```
#ifdef STAT
#define assign_trace(A, B)
    if (tracing_assigns > 0) restore_trace(A, B);
#else
#define assign_trace(A, B)
#endif
    static void eq_define(pointer p, quarterword t, halfword e)      ▷ new data for eqtb ◁
    { if (eTeX_ex ∧ (eq_type(p) ≡ t) ∧ (equiv(p) ≡ e)) { assign_trace(p, "reassigning")
        eq_destroy(eqtb[p]); return;
    }
    assign_trace(p, "changing")
    if (eq_level(p) ≡ cur_level) eq_destroy(eqtb[p]);
    else if (cur_level > level_one) eq_save(p, eq_level(p));
    eq_level(p) ← cur_level; eq_type(p) ← t; equiv(p) ← e;
    if (p ≡ par_shape_loc) {
        par_shape_hfactor ← cur_hfactor; par_shape_vfactor ← cur_vfactor;
    }
    assign_trace(p, "into")
}
```

278. The counterpart of *eq_define* for the remaining (fullword) positions in *eqtb* is called *eq_word_define*. Since *xeq_level*[p] ≥ *level_one* for all p, a '*restore_zero*' will never be used in this case.

```
    static void eq_word_define(pointer p, int w)
    { assign_trace(p, "changing")
    if (cur_level ≡ level_one) {
        if (p ≡ dimen_base + hsize_code) {
            hhsize ← w + round(((double) cur_hfactor * hhsize + (double) cur_vfactor * hvsize)/unity);
            return; }
        if (p ≡ dimen_base + vsize_code) {
            hvsize ← w + round(((double) cur_hfactor * hhsize + (double) cur_vfactor * hvsize)/unity);
            return; }
    }
    if (xeq_level[p] ≠ cur_level) { eq_save(p, xeq_level[p]); xeq_level[p] ← cur_level;
    }
    eqtb[p].i ← w;
    if (p ≥ dimen_base) {
        hfactor_eqtb[p].i ← cur_hfactor; vfactor_eqtb[p].i ← cur_vfactor;
    }
    assign_trace(p, "into")
}
```

279.   The *eq_define* and *eq_word_define* routines take care of local definitions. Global definitions are done in almost the same way, but there is no need to save old values, and the new value is associated with *level_one*.

> **static void** *geq_define*(**pointer** p, **quarterword** t, **halfword** e)   ▷ global *eq_define* ◁
> { *assign_trace*(p, "globally␣changing")
>   { *eq_destroy*(*eqtb*[p]); *eq_level*(p) ← *level_one*; *eq_type*(p) ← t; *equiv*(p) ← e;
>   }
>   *assign_trace*(p, "into");
> }
>
> **static void** *geq_word_define*(**pointer** p, **int** w)   ▷ global *eq_word_define* ◁
> { *assign_trace*(p, "globally␣changing")
>   {
>   *xeq_level*[p] ← *level_one*;
>   **if** ($p \equiv dimen\_base + hsize\_code$)
>   *hhsize* ← $w + round(((\textbf{double})\ cur\_hfactor * hhsize + (\textbf{double})\ cur\_vfactor * hvsize)/unity)$;
>   **else if** ($p \equiv dimen\_base + vsize\_code$)
>   *hvsize* ← $w + round(((\textbf{double})\ cur\_hfactor * hhsize + (\textbf{double})\ cur\_vfactor * hvsize)/unity)$;
>   **else** {
>   *eqtb*[p].i ← w;
>   **if** ($p \geq dimen\_base$) {
>   *hfactor_eqtb*[p].i ← *cur_hfactor*; *vfactor_eqtb*[p].i ← *cur_vfactor*;
>   }
>   }
>   }
>   }
>   *assign_trace*(p, "into");
> }

280.   Subroutine *save_for_after* puts a token on the stack for save-keeping.

> **static void** *save_for_after*(**halfword** t)
> { **if** ($cur\_level > level\_one$) { *check_full_save_stack*; *save_type*(*save_ptr*) ← *insert_token*;
>   *save_level*(*save_ptr*) ← *level_zero*; *save_index*(*save_ptr*) ← t; *incr*(*save_ptr*);
>   }
> }

281.   The *unsave* routine goes the other way, taking items off of *save_stack*. This routine takes care of restoration when a level ends; everything belonging to the topmost group is cleared off of the save stack.

> **static void** *back_input*(**void**);
>
> **static void** *unsave*(**void**)   ▷ pops the top level off the save stack ◁
> { **pointer** p;   ▷ position to be restored ◁

See also sections 1393, 1394, 1440, 1441, 1458, 1460, 1461, 1505, 1507, 1521, 1522, 1523, 1524, and 1525.
This code is used in section 268.

285.   When looking for possible pointers to a memory location, it is helpful to look for references from *eqtb* that might be waiting on the save stack. Of course, we might find spurious pointers too; but this routine is merely an aid when debugging, and at such times we are grateful for any scraps of information, even if they prove to be irrelevant.

⟨ Search *save_stack* for equivalents that point to p 285 ⟩ ≡
 if ($save\_ptr > 0$)
  for ($q \leftarrow 0$; $q \leq save\_ptr - 1$; $q\mathord{+}\mathord{+}$) { **if** ($equiv\_field(save\_stack[q]) \equiv p$) { $print\_nl("\texttt{SAVE(}");$
   $print\_int(q);$ $print\_char(')');$
  }
 }

This code is used in section 172.

286.   Most of the parameters kept in *eqtb* can be changed freely, but there's an exception: The magnification should not be used with two different values during any TEX job, since a single magnification is applied to an entire run. The global variable *mag_set* is set to the current magnification whenever it becomes necessary to "freeze" it at a particular value.

⟨ Global variables 13 ⟩ +≡
 static int mag_set; ▷ if nonzero, this magnification should be used henceforth ◁

287.   ⟨ Set initial values of key variables 21 ⟩ +≡
 $mag\_set \leftarrow 0;$

288.   The *prepare_mag* subroutine is called whenever TEX wants to use *mag* for magnification.
 static void $prepare\_mag(\textbf{void})$
 { **if** (($mag\_set > 0$) ∧ ($mag \neq mag\_set$)) { $print\_err("\texttt{Incompatible\_magnification\_(}");$

  $help1("\texttt{The\_magnification\_ratio\_must\_be\_between\_1\_and\_32768.}");$ $int\_error(mag);$
  $geq\_word\_define(int\_base + mag\_code, 1000);$
 }
 $mag\_set \leftarrow mag;$
 }

289.   Token lists.   A TeX token is either a character or a control sequence, and it is represented internally in one of two ways: (1) A character whose ASCII code number is c and whose command code is m is represented as the number $2^8 m + c$; the command code is in the range $1 \leq m \leq 14$. (2) A control sequence whose *eqtb* address is p is represented as the number *cs_token_flag*$+p$. Here *cs_token_flag* $\equiv 2^{12} - 1$ is larger than $2^8 m + c$, yet it is small enough that *cs_token_flag* $+ p < max\_halfword$; thus, a token fits comfortably in a halfword.

A token t represents a *left_brace* command if and only if $t < left\_brace\_limit$; it represents a *right_brace* command if and only if we have $left\_brace\_limit \leq t < right\_brace\_limit$; and it represents a *match* or *end_match* command if and only if $match\_token \leq t \leq end\_match\_token$. The following definitions take care of these token-oriented constants and a few others.

#**define** *cs_token_flag* °*7777*   ▷ amount added to the *eqtb* location in a token that stands for a control sequence; is a multiple of 256, less 1 ◁

#**define** *left_brace_token* °*0400*   ▷ $2^8 \cdot left\_brace$ ◁

#**define** *left_brace_limit* °*1000*   ▷ $2^8 \cdot (left\_brace + 1)$ ◁

#**define** *right_brace_token* °*1000*   ▷ $2^8 \cdot right\_brace$ ◁

#**define** *right_brace_limit* °*1400*   ▷ $2^8 \cdot (right\_brace + 1)$ ◁

#**define** *math_shift_token* °*1400*   ▷ $2^8 \cdot math\_shift$ ◁

#**define** *tab_token* °*2000*   ▷ $2^8 \cdot tab\_mark$ ◁

#**define** *out_param_token* °*2400*   ▷ $2^8 \cdot out\_param$ ◁

#**define** *space_token* °*5040*   ▷ $2^8 \cdot spacer + $ '␣' ◁

#**define** *letter_token* °*5400*   ▷ $2^8 \cdot letter$ ◁

#**define** *other_token* °*6000*   ▷ $2^8 \cdot other\_char$ ◁

#**define** *match_token* °*6400*   ▷ $2^8 \cdot match$ ◁

#**define** *end_match_token* °*7000*   ▷ $2^8 \cdot end\_match$ ◁

#**define** *protected_token* °*7001*   ▷ $2^8 \cdot end\_match + 1$ ◁

290.   ⟨ Check the "constant" values for consistency 14 ⟩ +≡
    if $(cs\_token\_flag + undefined\_control\_sequence > max\_halfword)$ *bad* ← 21;

291. A token list is a singly linked list of one-word nodes in *mem*, where each word contains a token and a link. Macro definitions, output-routine definitions, marks, \write texts, and a few other things are remembered by TEX in the form of token lists, usually preceded by a node with a reference count in its *token_ref_count* field. The token stored in location p is called *info*(p).

Three special commands appear in the token lists of macro definitions. When $m \equiv match$, it means that TEX should scan a parameter for the current macro; when $m \equiv end\_match$, it means that parameter matching should end and TEX should start reading the macro text; and when $m \equiv out\_param$, it means that TEX should insert parameter number c into the text at this point.

The enclosing { and } characters of a macro definition are omitted, but an output routine will be enclosed in braces.

Here is an example macro definition that illustrates these conventions. After TEX processes the text

$$\text{\textbackslash def\textbackslash mac a\#1\#2 \textbackslash b \{\#1\textbackslash-a \#\#1\#2 \#2\}}$$

the definition of \mac is represented as a token list containing

(reference count), *letter* a, *match* #, *match* #, *spacer* ␣, \b, *end_match*,
out_param 1, \-, *letter* a, *spacer* ␣, *mac_param* #, *other_char* 1,
out_param 2, *spacer* ␣, *out_param* 2.

The procedure *scan_toks* builds such token lists, and *macro_call* does the parameter matching.

Examples such as

$$\text{\textbackslash def\textbackslash m\{\textbackslash def\textbackslash m\{a\}\textsubscript{␣}b\}}$$

explain why reference counts would be needed even if TEX had no \let operation: When the token list for \m is being read, the redefinition of \m changes the *eqtb* entry before the token list has been fully consumed, so we dare not simply destroy a token list when its control sequence is being redefined.

If the parameter-matching part of a definition ends with '#{', the corresponding token list will have '{' just before the '*end_match*' and also at the very end. The first '{' is used to delimit the parameter; the second one keeps the first from disappearing.

292.   The procedure *show_token_list*, which prints a symbolic form of the token list that starts at a given node p, illustrates these conventions. The token list being displayed should not begin with a reference count. However, the procedure is intended to be robust, so that if the memory links are awry or if p is not really a pointer to a token list, nothing catastrophic will happen.

An additional parameter q is also given; this parameter is either null or it points to a node in the token list where a certain magic computation takes place that will be explained later. (Basically, q is non-null when we are printing the two-line context information at the time of an error message; q marks the place corresponding to where the second line should begin.)

For example, if p points to the node containing the first a in the token list above, then *show_token_list* will print the string

<div align="center">'a#1#2␣\b␣->#1\-a␣##1#2␣#2';</div>

and if q points to the node containing the second a, the magic computation will be performed just before the second a is printed.

The generation will stop, and '\ETC.' will be printed, if the length of printing exceeds a given limit l. Anomalous entries are printed in the form of control sequences that are not followed by a blank space, e.g., '\BAD.'; this cannot be confused with actual control sequences because a real control sequence named BAD would come out '\BAD␣'.

⟨ Declare the procedure called *show_token_list* 292 ⟩ ≡
  static void *show_token_list*(**int** p, **int** q, **int** l)
  { **int** m, c;   ▷ pieces of a token ◁
    ASCII_code *match_chr*;   ▷ character used in a '*match*' ◁
    ASCII_code n;   ▷ the highest parameter number, as an ASCII digit ◁

    match_chr ← '#'; n ← '0'; *tally* ← 0;
    while $((p \neq null) \wedge (tally < l))$ { **if** $(p \equiv q)$ ⟨ Do magic computation 320 ⟩;
      ⟨ Display token p, and **return** if there are problems 293 ⟩;
      $p \leftarrow link(p)$;
    }
    if $(p \neq null)$ *print_esc*("ETC.");
  }

This code is used in section 119.

293.   ⟨ Display token p, and **return** if there are problems 293 ⟩ ≡
  if $((p < hi\_mem\_min) \vee (p > mem\_end))$ { *print_esc*("CLOBBERED."); **return**;
  }
  if $(info(p) \geq cs\_token\_flag)$ *print_cs*$(info(p) - cs\_token\_flag)$;
  else { $m \leftarrow info(p)/°400$; $c \leftarrow info(p) \% °400$;
    if $(info(p) < 0)$ *print_esc*("BAD.");
    else ⟨ Display the token (m, c) 294 ⟩;
  }

This code is used in section 292.

294.   The procedure usually "learns" the character code used for macro parameters by seeing one in a *match* command before it runs into any *out_param* commands.

⟨ Display the token (m, c) 294 ⟩ ≡
  switch (m) {
  case *left_brace*: **case** *right_brace*: **case** *math_shift*: **case** *tab_mark*: **case** *sup_mark*: **case** *sub_mark*:
    case *spacer*: **case** *letter*: **case** *other_char*: *printn*(c); **break**;
  case *mac_param*:
    { *printn*(c); *printn*(c);
    } **break**;
  case *out_param*:
    { *printn*(*match_chr*);
      if $(c \leq 9)$ *print_char*$(c + \text{'0'})$;
      else { *print_char*('!'); **return**;
      }
    } **break**;
  case *match*:
    { *match_chr* ← c; *printn*(c); *incr*(n); *print_char*(n);
      if $(n > \text{'9'})$ **return**;
    } **break**;
  case *end_match*:
    if $(c \equiv 0)$ *print*("->"); **break**;
  default: *print_esc*("BAD.");
  }
This code is used in section 293.

295.   Here's the way we sometimes want to display a token list, given a pointer to its reference count; the pointer may be null.

  static void *token_show*(**pointer** *p*)
  { **if** $(p \neq null)$ *show_token_list*(*link*(p), *null*, 10000000);
  }

296.   The *print_meaning* subroutine displays *cur_cmd* and *cur_chr* in symbolic form, including the expansion of a macro or mark.

  static void *print_meaning*(**void**)
  { *print_cmd_chr*(*cur_cmd*, *cur_chr*);
    if $(cur\_cmd \geq call)$ { *print_char*(':'); *print_ln*( ); *token_show*(*cur_chr*);
    }
    else if $((cur\_cmd \equiv top\_bot\_mark) \wedge (cur\_chr < marks\_code))$ { *print_char*(':'); *print_ln*( );
      token_show(*cur_mark*[*cur_chr*]);
    }
  }

297. Introduction to the syntactic routines.   Let's pause a moment now and try to look at the Big Picture. The TeX program consists of three main parts: syntactic routines, semantic routines, and output routines. The chief purpose of the syntactic routines is to deliver the user's input to the semantic routines, one token at a time. The semantic routines act as an interpreter responding to these tokens, which may be regarded as commands. And the output routines are periodically called on to convert box-and-glue lists into a compact set of instructions that will be sent to a typesetter. We have discussed the basic data structures and utility routines of TeX, so we are good and ready to plunge into the real activity by considering the syntactic routines.

Our current goal is to come to grips with the *get_next* procedure, which is the keystone of TeX's input mechanism. Each call of *get_next* sets the value of three variables *cur_cmd*, *cur_chr*, and *cur_cs*, representing the next input token.

> *cur_cmd* denotes a command code from the long list of codes given above;
> *cur_chr* denotes a character code or other modifier of the command code;
> *cur_cs* is the *eqtb* location of the current control sequence,
>   if the current token was a control sequence, otherwise it's zero.

Underlying this external behavior of *get_next* is all the machinery necessary to convert from character files to tokens. At a given time we may be only partially finished with the reading of several files (for which \input was specified), and partially finished with the expansion of some user-defined macros and/or some macro parameters, and partially finished with the generation of some text in a template for \halign, and so on. When reading a character file, special characters must be classified as math delimiters, etc.; comments and extra blank spaces must be removed, paragraphs must be recognized, and control sequences must be found in the hash table. Furthermore there are occasions in which the scanning routines have looked ahead for a word like 'plus' but only part of that word was found, hence a few characters must be put back into the input and scanned again.

To handle these situations, which might all be present simultaneously, TeX uses various stacks that hold information about the incomplete activities, and there is a finite state control for each level of the input mechanism. These stacks record the current state of an implicitly recursive process, but the *get_next* procedure is not recursive. Therefore it will not be difficult to translate these algorithms into low-level languages that do not support recursion.

⟨ Global variables 13 ⟩ +≡
  static eight_bits *cur_cmd*;   ▷ current command set by *get_next* ◁
  static halfword *cur_chr*;   ▷ operand of current command ◁
  static pointer *cur_cs*;   ▷ control sequence found here, zero if none found ◁
  static halfword *cur_tok*;   ▷ packed representative of *cur_cmd* and *cur_chr* ◁

298. The $print\_cmd\_chr$ routine prints a symbolic interpretation of a command code and its modifier. This is used in certain 'You can´t' error messages, and in the implementation of diagnostic routines like \show.

The body of $print\_cmd\_chr$ is a rather tedious listing of print commands, and most of it is essentially an inverse to the $primitive$ routine that enters a TEX primitive into $eqtb$. Therefore much of this procedure appears elsewhere in the program, together with the corresponding $primitive$ calls.

#**define** $chr\_cmd(A)$
      { $print(A)$; $print\_ASCII(chr\_code)$;
      }

⟨ Declare the procedure called $print\_cmd\_chr$ 298 ⟩ ≡
  static void $print\_cmd\_chr$(**quarterword** cmd, **halfword** chr_code)
  { **int** n;   ▷ temp variable ◁

    switch (cmd) {
    case $left\_brace$: chr_cmd("begin-group␣character␣") **break**;
    case $right\_brace$: chr_cmd("end-group␣character␣") **break**;
    case $math\_shift$: chr_cmd("math␣shift␣character␣") **break**;
    case mac_param: chr_cmd("macro␣parameter␣character␣") **break**;
    case sup_mark: chr_cmd("superscript␣character␣") **break**;
    case sub_mark: chr_cmd("subscript␣character␣") **break**;
    case $endv$: $print$("end␣of␣alignment␣template"); **break**;
    case $spacer$: chr_cmd("blank␣space␣") **break**;
    case $letter$: chr_cmd("the␣letter␣") **break**;
    case $other\_char$: chr_cmd("the␣character␣") **break**;
    ⟨ Cases of $print\_cmd\_chr$ for symbolic printing of primitives 227 ⟩
    default: $print$("[unknown␣command␣code!]");
    }
  }

This code is used in section 252.

299.   Here is a procedure that displays the current command.

```
static void show_cur_cmd_chr(void)
{ int n;      ▷ level of \if...\fi nesting ◁
  int l;      ▷ line where \if started ◁
  pointer p;

  begin_diagnostic(); print_nl("{");
  if (mode ≠ shown_mode) { print_mode(mode); print(":␣"); shown_mode ← mode;
  }
  print_cmd_chr(cur_cmd, cur_chr);
  if (tracing_ifs > 0)
    if (cur_cmd ≥ if_test)
      if (cur_cmd ≤ fi_or_else) { print(":␣");
        if (cur_cmd ≡ fi_or_else) { print_cmd_chr(if_test, cur_if); print_char('␣'); n ← 0;
          l ← if_line;
        }
        else { n ← 1; l ← line;
        }
        p ← cond_ptr;
        while (p ≠ null) { incr(n); p ← link(p);
        }
        print("(level␣"); print_int(n); print_char(')'); print_if_line(l);
      }
  print_char('}'); end_diagnostic(false);
}
```

300.   Input stacks and states.   This implementation of TₑX uses two different conventions for representing sequential stacks.

1) If there is frequent access to the top entry, and if the stack is essentially never empty, then the top entry is kept in a global variable (even better would be a machine register), and the other entries appear in the array $stack[0 \to (ptr - 1)]$. For example, the semantic stack described above is handled this way, and so is the input stack that we are about to study.

2) If there is infrequent top access, the entire stack contents are in the array $stack[0 \to (ptr - 1)]$. For example, the *save_stack* is treated this way, as we have seen.

The state of TₑX's input mechanism appears in the input stack, whose entries are records with six fields, called *state*, *index*, *start*, *loc*, *limit*, and *name*. This stack is maintained with convention (1), so it is declared in the following way:

⟨ Types in the outer block 18 ⟩ +≡
  typedef struct {
    quarterword *state_field*, *index_field*;
    halfword *start_field*, *loc_field*, *limit_field*, *name_field*;
  } **in_state_record**;

301.   ⟨ Global variables 13 ⟩ +≡
  static in_state_record *input_stack*[*stack_size* + 1];
  static int *input_ptr*;   ▷ first unused location of *input_stack* ◁
  static int *max_in_stack*;   ▷ largest value of *input_ptr* when pushing ◁
  static in_state_record *cur_input*;   ▷ the "top" input state, according to convention (1) ◁

302.   We've already defined the special variable *loc* ≡≡ *cur_input.loc_field* in our discussion of basic input-output routines. The other components of *cur_input* are defined in the same way:

#**define** *state* *cur_input.state_field*   ▷ current scanner state ◁
#**define** *index* *cur_input.index_field*   ▷ reference for buffer information ◁
#**define** *start* *cur_input.start_field*   ▷ starting position in *buffer* ◁
#**define** *limit* *cur_input.limit_field*   ▷ end of current line in *buffer* ◁
#**define** *name* *cur_input.name_field*   ▷ name of the current file ◁

303.   Let's look more closely now at the control variables ($state$, $index$, $start$, loc, $limit$, $name$), assuming that TeX is reading a line of characters that have been input from some file or from the user's terminal. There is an array called $buffer$ that acts as a stack of all lines of characters that are currently being read from files, including all lines on subsidiary levels of the input stack that are not yet completed. TeX will return to the other lines when it is finished with the present input file.

(Incidentally, on a machine with byte-oriented addressing, it might be appropriate to combine $buffer$ with the str_pool array, letting the buffer entries grow downward from the top of the string pool and checking that these two tables don't bump into each other.)

The line we are currently working on begins in position $start$ of the buffer; the next character we are about to read is $buffer[loc]$; and $limit$ is the location of the last character present. If $loc > limit$, the line has been completely read. Usually $buffer[limit]$ is the end_line_char, denoting the end of a line, but this is not true if the current line is an insertion that was entered on the user's terminal in response to an error message.

The $name$ variable is a string number that designates the name of the current file, if we are reading a text file. It is zero if we are reading from the terminal; it is $n + 1$ if we are reading from input stream n, where $0 \le n \le 16$. (Input stream 16 stands for an invalid stream number; in such cases the input is actually from the terminal, under control of the procedure $read\_toks$.) Finally $18 \le name \le 19$ indicates that we are reading a pseudo file created by the \scantokens command.

The $state$ variable has one of three values, when we are scanning such files:

> 1) $state \equiv mid\_line$ is the normal state.
>
> 2) $state \equiv skip\_blanks$ is like mid_line, but blanks are ignored.
>
> 3) $state \equiv new\_line$ is the state at the beginning of a line.

These state values are assigned numeric codes so that if we add the state code to the next character's command code, we get distinct values. For example, '$mid\_line + spacer$' stands for the case that a blank space character occurs in the middle of a line when it is not being ignored; after this case is processed, the next value of $state$ will be $skip\_blanks$.

#**define** mid_line 1   ▷ $state$ code when scanning a line of characters ◁
#**define** $skip\_blanks$ $(2 + max\_char\_code)$ ▷ $state$ code when ignoring blanks ◁
#**define** new_line $(3 + max\_char\_code + max\_char\_code)$ ▷ $state$ code at start of line ◁

304.   Additional information about the current line is available via the *index* variable, which counts how many lines of characters are present in the buffer below the current level. We have $index \equiv 0$ when reading from the terminal and prompting the user for each line; then if the user types, e.g., '`\input paper`', we will have $index \equiv 1$ while reading the file `paper.tex`. However, it does not follow that *index* is the same as the input stack pointer, since many of the levels on the input stack may come from token lists. For example, the instruction '`\input paper`' might occur in a token list.

The global variable *in_open* is equal to the *index* value of the highest non-token-list level. Thus, the number of partially read lines in the buffer is $in\_open + 1$, and we have $in\_open \equiv index$ when we are not reading a token list.

If we are not currently reading from the terminal, or from an input stream, we are reading from the file variable *input_file*[*index*]. We use the notation *terminal_input* as a convenient abbreviation for $name \equiv 0$, and *cur_file* as an abbreviation for *input_file*[*index*].

The global variable *line* contains the line number in the topmost open file, for use in error messages. If we are not reading from the terminal, *line_stack*[*index*] holds the line number for the enclosing level, so that *line* can be restored when the current file has been read. Line numbers should never be negative, since the negative of the current line number is used to identify the user's output routine in the *mode_line* field of the semantic nest entries.

If more information about the input state is needed, it can be included in small arrays like those shown here. For example, the current page or segment number in the input file might be put into a variable *page*, maintained for enclosing levels in '*page_stack*: *array*[1 .. *max_in_open*] **int**' by analogy with *line_stack*.

#**define** *terminal_input*   ($name \equiv 0$)   ▷ are we reading from the terminal? ◁
#**define** *cur_file*   *input_file*[*index*]   ▷ the current **alpha_file** variable ◁

⟨ Global variables 13 ⟩ +≡
   static int *in_open*;   ▷ the number of lines in the buffer, less one ◁
   static int *open_parens*;   ▷ the number of open text files ◁
   static alpha_file *input_file0*[*max_in_open*], ∗**const** *input_file* ← *input_file0* − 1;
   static int *line*;   ▷ current line number in the current source file ◁
   static int *line_stack0*[*max_in_open*], ∗**const** *line_stack* ← *line_stack0* − 1;

305.   Users of TeX sometimes forget to balance left and right braces properly, and one of the ways TeX tries to spot such errors is by considering an input file as broken into subfiles by control sequences that are declared to be \outer.

A variable called *scanner_status* tells TeX whether or not to complain when a subfile ends. This variable has six possible values:

normal, means that a subfile can safely end here without incident.

skipping, means that a subfile can safely end here, but not a file, because we're reading past some conditional text that was not selected.

defining, means that a subfile shouldn't end now because a macro is being defined.

matching, means that a subfile shouldn't end now because a macro is being used and we are searching for the end of its arguments.

aligning, means that a subfile shouldn't end now because we are not finished with the preamble of an \halign or \valign.

absorbing, means that a subfile shouldn't end now because we are reading a balanced token list for \message, \write, etc.

If the *scanner_status* is not *normal*, the variable *warning_index* points to the *eqtb* location for the relevant control sequence name to print in an error message.

#**define** *skipping*   1   ▷ *scanner_status* when passing conditional text ◁
#**define** *defining*   2   ▷ *scanner_status* when reading a macro definition ◁
#**define** *matching*   3   ▷ *scanner_status* when reading macro arguments ◁
#**define** *aligning*   4   ▷ *scanner_status* when reading an alignment preamble ◁
#**define** *absorbing* 5   ▷ *scanner_status* when reading a balanced text ◁

⟨ Global variables 13 ⟩ +≡
  static int *scanner_status*;   ▷ can a subfile end now? ◁
  static pointer *warning_index*;   ▷ identifier relevant to non-*normal* scanner status ◁
  static pointer *def_ref*;   ▷ reference count of token list being defined ◁

306.   Here is a procedure that uses *scanner_status* to print a warning message when a subfile has ended, and at certain other crucial times:

⟨ Declare the procedure called *runaway* 306 ⟩ ≡
  static void *runaway*(**void**)
  { **pointer** *p*;   ▷ head of runaway list ◁

    if (*scanner_status* > *skipping*) { *print_nl*("Runaway␣");
      switch (*scanner_status*) {
      case *defining*:
        { *print*("definition"); *p* ← *def_ref*;
        } **break**;
      case *matching*:
        { *print*("argument"); *p* ← *temp_head*;
        } **break**;
      case *aligning*:
        { *print*("preamble"); *p* ← *hold_head*;
        } **break**;
      case *absorbing*:
        { *print*("text"); *p* ← *def_ref*;
        }
      }   ▷ there are no other cases ◁
      print_char('?'); *print_ln*(); *show_token_list*(*link*(*p*), *null*, *error_line* − 10);
    }
  }

This code is used in section 119.

307.   However, all this discussion about input state really applies only to the case that we are inputting from a file. There is another important case, namely when we are currently getting input from a token list. In this case *state* ≡ *token_list*, and the conventions about the other state variables are different:

loc is a pointer to the current node in the token list, i.e., the node that will be read next. If *loc* ≡ *null*, the token list has been fully read.

start points to the first node of the token list; this node may or may not contain a reference count, depending on the type of token list involved.

token_type, which takes the place of *index* in the discussion above, is a code number that explains what kind of token list is being scanned.

name points to the *eqtb* address of the control sequence being expanded, if the current token list is a macro.

param_start, which takes the place of *limit*, tells where the parameters of the current macro begin in the *param_stack*, if the current token list is a macro.

The *token_type* can take several values, depending on where the current token list came from:

parameter, if a parameter is being scanned;
u_template, if the ⟨u_j⟩ part of an alignment template is being scanned;
v_template, if the ⟨v_j⟩ part of an alignment template is being scanned;
backed_up, if the token list being scanned has been inserted as 'to be read again';
inserted, if the token list being scanned has been inserted as the text expansion of a \count or similar variable;
macro, if a user-defined control sequence is being scanned;
output_text, if an \output routine is being scanned;
every_par_text, if the text of \everypar is being scanned;
every_math_text, if the text of \everymath is being scanned;
every_display_text, if the text of \everydisplay is being scanned;
every_hbox_text, if the text of \everyhbox is being scanned;
every_vbox_text, if the text of \everyvbox is being scanned;
every_job_text, if the text of \everyjob is being scanned;
every_cr_text, if the text of \everycr is being scanned;
mark_text, if the text of a \mark is being scanned;
write_text, if the text of a \write is being scanned.

The codes for *output_text*, *every_par_text*, etc., are equal to a constant plus the corresponding codes for token list parameters *output_routine_loc*, *every_par_loc*, etc. The token list begins with a reference count if and only if *token_type* ≥ *macro*.

   Since ε-TeX's additional token list parameters precede *toks_base*, the corresponding token types must precede *write_text*.

#**define** *token_list* 0   ▷ *state* code when scanning a token list ◁
#**define** *token_type* *index*   ▷ type of current token list ◁
#**define** *param_start* *limit*   ▷ base of macro parameters in *param_stack* ◁

#**define** *every_job_text* 12   ▷ *token_type* code for \everyjob ◁
#**define** *every_cr_text* 13   ▷ *token_type* code for \everycr ◁
#**define** *mark_text* 14   ▷ *token_type* code for \topmark, etc. ◁
#**define** *eTeX_text_offset* (*output_routine_loc* − *output_text*)
#**define** *every_eof_text* (*every_eof_loc* − *eTeX_text_offset*)   ▷ *token_type* code for \everyeof ◁
#**define** *write_text* (*toks_base* − *eTeX_text_offset*)   ▷ *token_type* code for \write ◁

308.   The *param_stack* is an auxiliary array used to hold pointers to the token lists for parameters at the current level and subsidiary levels of input. This stack is maintained with convention (2), and it grows at a different rate from the others.

⟨ Global variables 13 ⟩ +≡
   static pointer *param_stack*[*param_size* + 1];   ▷ token list pointers for parameters ◁
   static int *param_ptr*;   ▷ first unused entry in *param_stack* ◁
   static int *max_param_stack*;   ▷ largest value of *param_ptr*, will be ≤ *param_size* + 9 ◁

309.   The input routines must also interact with the processing of \halign and \valign, since the appearance of tab marks and \cr in certain places is supposed to trigger the beginning of special ⟨v_j⟩ template text in the scanner. This magic is accomplished by an *align_state* variable that is increased by 1 when a '{' is scanned and decreased by 1 when a '}' is scanned. The *align_state* is nonzero during the ⟨u_j⟩ template, after which it is set to zero; the ⟨v_j⟩ template begins when a tab mark or \cr occurs at a time that *align_state* ≡ 0.
   The same principle applies when entering the definition of a control sequence between \csname and \endcsname.

⟨ Global variables 13 ⟩ +≡
   static int *align_state*;   ▷ group level with respect to current alignment ◁
   static int *incsname_state*;   ▷ group level with respect to in csname state ◁

310.   Thus, the "current input state" can be very complicated indeed; there can be many levels and each level can arise in a variety of ways. The *show_context* procedure, which is used by TeX's error-reporting routine to print out the current input state on all levels down to the most recent line of characters from an input file, illustrates most of these conventions. The global variable *base_ptr* contains the lowest level that was displayed by this procedure.

⟨ Global variables 13 ⟩ +≡
   static int *base_ptr*;   ▷ shallowest level shown by *show_context* ◁

311.   The status at each level is indicated by printing two lines, where the first line indicates what was read so far and the second line shows what remains to be read. The context is cropped, if necessary, so that the first line contains at most *half_error_line* characters, and the second contains at most *error_line*. Non-current input levels whose *token_type* is '*backed_up*' are shown only if they have not been fully read.

> static void *show_context*(**void**)   ▷ prints where the scanner is ◁
> { **int** *old_setting*;   ▷ saved *selector* setting ◁
>   **int** *nn*;   ▷ number of contexts shown so far, less one ◁
>   **bool** *bottom_line*;   ▷ have we reached the final context to be shown? ◁
>
>   ⟨Local variables for formatting calculations 315⟩
>   *base_ptr* ← *input_ptr*; *input_stack*[*base_ptr*] ← *cur_input*;   ▷ store current state ◁
>   *nn* ← −1; *bottom_line* ← *false*;
>   **loop** { *cur_input* ← *input_stack*[*base_ptr*];   ▷ enter into the context ◁
>   **if** ((*state* ≠ *token_list*))
>   **if** ((*name* > 19) ∨ (*base_ptr* ≡ 0)) *bottom_line* ← *true*;
>   **if** ((*base_ptr* ≡ *input_ptr*) ∨ *bottom_line* ∨ (*nn* < *error_context_lines*))
>   ⟨Display the current context 312⟩
>   **else if** (*nn* ≡ *error_context_lines*) { *print_nl*("..."); *incr*(*nn*);
>   ▷ omitted if *error_context_lines* < 0 ◁
>   }
>   **if** (*bottom_line*) **goto** *done*;
>   *decr*(*base_ptr*);
>   }
> *done*: *cur_input* ← *input_stack*[*input_ptr*];   ▷ restore original state ◁
> }

312.   ⟨Display the current context 312⟩ ≡
>   { **if** ((*base_ptr* ≡ *input_ptr*) ∨ (*state* ≠ *token_list*) ∨ (*token_type* ≠ *backed_up*) ∨ (*loc* ≠ *null*))
>   ▷ we omit backed-up token lists that have already been read ◁
>   { *tally* ← 0;   ▷ get ready to count characters ◁
>   *old_setting* ← *selector*;
>   **if** (*state* ≠ *token_list*) { ⟨Print location of current line 313⟩;
>   ⟨Pseudoprint the line 318⟩;
>   }
>   **else** { ⟨Print type of token list 314⟩;
>   ⟨Pseudoprint the token list 319⟩;
>   }
>   *selector* ← *old_setting*;   ▷ stop pseudoprinting ◁
>   ⟨Print two lines using the tricky pseudoprinted information 317⟩;
>   *incr*(*nn*);
>   }
>   }

This code is used in section 311.

313.   This routine should be changed, if necessary, to give the best possible indication of where the current line resides in the input file. For example, on some systems it is best to print both a page and line number.

⟨ Print location of current line 313 ⟩ ≡

  if (*name* ≤ 17)
    if (*terminal_input*)
      if (*base_ptr* ≡ 0) *print_nl*("<*>");
      else *print_nl*("<insert>␣");
    else { *print_nl*("<read␣");
      if (*name* ≡ 17) *print_char*('*'); **else** *print_int*(*name* − 1);
      print_char('>');
    }
  else { *print_nl*("l.");
    if (*index* ≡ *in_open*) *print_int*(*line*);
    else *print_int*(*line_stack*[*index* + 1]);   ▷ input from a pseudo file ◁
  }
  print_char('␣')

This code is used in section 312.

314.   ⟨ Print type of token list 314 ⟩ ≡

  switch (*token_type*) {
  case *parameter*: *print_nl*("<argument>␣"); **break**;
  case *u_template*: **case** *v_template*: *print_nl*("<template>␣"); **break**;
  case *backed_up*:
    if (*loc* ≡ *null*) *print_nl*("<recently␣read>␣");
    else *print_nl*("<to␣be␣read␣again>␣"); **break**;
  case *inserted*: *print_nl*("<inserted␣text>␣"); **break**;
  case *macro*:
    { *print_ln*( ); *print_cs*(*name*);
    } **break**;
  case *output_text*: *print_nl*("<output>␣"); **break**;
  case *every_par_text*: *print_nl*("<everypar>␣"); **break**;
  case *every_math_text*: *print_nl*("<everymath>␣"); **break**;
  case *every_display_text*: *print_nl*("<everydisplay>␣"); **break**;
  case *every_hbox_text*: *print_nl*("<everyhbox>␣"); **break**;
  case *every_vbox_text*: *print_nl*("<everyvbox>␣"); **break**;
  case *every_job_text*: *print_nl*("<everyjob>␣"); **break**;
  case *every_cr_text*: *print_nl*("<everycr>␣"); **break**;
  case *mark_text*: *print_nl*("<mark>␣"); **break**;
  case *every_eof_text*: *print_nl*("<everyeof>␣"); **break**;
  case *write_text*: *print_nl*("<write>␣"); **break**;
  default: *print_nl*("?");   ▷ this should never happen ◁
  }

This code is used in section 312.

315.   Here it is necessary to explain a little trick. We don't want to store a long string that corresponds to a token list, because that string might take up lots of memory; and we are printing during a time when an error message is being given, so we dare not do anything that might overflow one of TₑX's tables. So 'pseudoprinting' is the answer: We enter a mode of printing that stores characters into a buffer of length $error\_line$, where character $k+1$ is placed into $trick\_buf[k \% error\_line]$ if $k < trick\_count$, otherwise character k is dropped. Initially we set $tally \leftarrow 0$ and $trick\_count \leftarrow 1000000$; then when we reach the point where transition from line 1 to line 2 should occur, we set $first\_count \leftarrow tally$ and $trick\_count \leftarrow \max(error\_line, tally + 1 + error\_line - half\_error\_line)$. At the end of the pseudoprinting, the values of $first\_count$, $tally$, and $trick\_count$ give us all the information we need to print the two lines, and all of the necessary text is in $trick\_buf$.

Namely, let l be the length of the descriptive information that appears on the first line. The length of the context information gathered for that line is $k \equiv first\_count$, and the length of the context information gathered for line 2 is $m = \min(tally, trick\_count) - k$. If $l + k \leq h$, where $h \equiv half\_error\_line$, we print $trick\_buf[0 .. k-1]$ after the descriptive information on line 1, and set $n \leftarrow l + k$; here n is the length of line 1. If $l + k > h$, some cropping is necessary, so we set $n \leftarrow h$ and print '...' followed by

$$trick\_buf[(l + k - h + 3) .. k - 1],$$

where subscripts of $trick\_buf$ are circular modulo $error\_line$. The second line consists of n spaces followed by $trick\_buf[k .. (k + m - 1)]$, unless $n + m > error\_line$; in the latter case, further cropping is done. This is easier to program than to explain.

⟨ Local variables for formatting calculations 315 ⟩ ≡
   int i;   ▷ index into $buffer$ ◁
   int j;   ▷ end of current line in $buffer$ ◁
   int l;   ▷ length of descriptive information on line 1 ◁
   int m;   ▷ context information gathered for line 2 ◁
   int n;   ▷ length of line 1 ◁
   int p;   ▷ starting or ending place in $trick\_buf$ ◁
   int q;   ▷ temporary index ◁
This code is used in section 311.

316.   The following code sets up the print routines so that they will gather the desired information.

#**define** $begin\_pseudoprint$
      { $l \leftarrow tally$; $tally \leftarrow 0$; $selector \leftarrow pseudo$; $trick\_count \leftarrow 1000000$;
      }
#**define** set_trick_count
      { $first\_count \leftarrow tally$; $trick\_count \leftarrow tally + 1 + error\_line - half\_error\_line$;
        if ($trick\_count < error\_line$) $trick\_count \leftarrow error\_line$;
      }

317.   And the following code uses the information after it has been gathered.

⟨ Print two lines using the tricky pseudoprinted information 317 ⟩ ≡
   if (*trick_count* ≡ 1000000) *set_trick_count*;   ▷ *set_trick_count* must be performed ◁
   if (*tally* < *trick_count*) *m* ← *tally* − *first_count*;
   else *m* ← *trick_count* − *first_count*;   ▷ context on line 2 ◁
   if (*l* + *first_count* ≤ *half_error_line*) { *p* ← 0; *n* ← *l* + *first_count*;
   }
   else { *print*("..."); *p* ← *l* + *first_count* − *half_error_line* + 3; *n* ← *half_error_line*;
   }
   for (*q* ← *p*; *q* ≤ *first_count* − 1; *q*++) *print_char*(*trick_buf*[*q* % *error_line*]);
   print_ln( );
   for (*q* ← 1; *q* ≤ *n*; *q*++) *print_char*('␣');   ▷ print *n* spaces to begin line 2 ◁
   if (*m* + *n* ≤ *error_line*) *p* ← *first_count* + *m*;
   else *p* ← *first_count* + (*error_line* − *n* − 3);
   for (*q* ← *first_count*; *q* ≤ *p* − 1; *q*++) *print_char*(*trick_buf*[*q* % *error_line*]);
   if (*m* + *n* > *error_line*) *print*("...")
This code is used in section 312.

318.   But the trick is distracting us from our current goal, which is to understand the input state. So let's
concentrate on the data structures that are being pseudoprinted as we finish up the *show_context* procedure.

⟨ Pseudoprint the line 318 ⟩ ≡
   begin_pseudoprint;
   if (*buffer*[*limit*] ≡ *end_line_char*) *j* ← *limit*;
   else *j* ← *limit* + 1;   ▷ determine the effective end of the line ◁
   if (*j* > 0)
      for (*i* ← *start*; *i* ≤ *j* − 1; *i*++) { **if** (*i* ≡ *loc*) *set_trick_count*;
         printn(*buffer*[*i*]);
      }
This code is used in section 312.

319.   ⟨ Pseudoprint the token list 319 ⟩ ≡
   begin_pseudoprint;
   if (*token_type* < *macro*) *show_token_list*(*start*, *loc*, 100000);
   else *show_token_list*(*link*(*start*), *loc*, 100000)   ▷ avoid reference count ◁
This code is used in section 312.

320.   Here is the missing piece of *show_token_list* that is activated when the token beginning line 2 is about
to be shown:

⟨ Do magic computation 320 ⟩ ≡
   set_trick_count
This code is used in section 292.

321.   Maintaining the input stacks.   The following subroutines change the input status in commonly needed ways.

First comes *push_input*, which stores the current state and creates a new level (having, initially, the same properties as the old).

#**define** *push_input*   ▷ enter a new input level, save the old ◁
            { **if** (*input_ptr* > *max_in_stack*) { *max_in_stack* ← *input_ptr*;
                if (*input_ptr* ≡ *stack_size*) *overflow*("input␣stack␣size", *stack_size*);
              }
              input_stack[*input_ptr*] ← *cur_input*;   ▷ stack the record ◁
              incr(*input_ptr*);
            }

322.   And of course what goes up must come down.

#**define** *pop_input*   ▷ leave an input level, re-enter the old ◁
          { *decr*(*input_ptr*); *cur_input* ← *input_stack*[*input_ptr*];
          }

323.   Here is a procedure that starts a new level of token-list input, given a token list p and its type t. If $t \equiv macro$, the calling routine should set *name* and *loc*.

#**define** *back_list*(*A*)   *begin_token_list*(*A*, *backed_up*)   ▷ backs up a simple token list ◁
#**define** *ins_list*(*A*)   *begin_token_list*(*A*, *inserted*)   ▷ inserts a simple token list ◁
    static void *begin_token_list*(**pointer** *p*, **quarterword** *t*)
  { *push_input*; *state* ← *token_list*; *start* ← *p*; *token_type* ← *t*;
    if (*t* ≥ *macro*)   ▷ the token list starts with a reference count ◁
    { *add_token_ref*(*p*);
      if (*t* ≡ *macro*) *param_start* ← *param_ptr*;
      else { *loc* ← *link*(*p*);
        if (*tracing_macros* > 1) { *begin_diagnostic*( ); *print_nl*("");
          switch (*t*) {
          case *mark_text*: *print_esc*("mark"); **break**;
          case *write_text*: *print_esc*("write"); **break**;
          default: *print_cmd_chr*(*assign_toks*, *t* − *output_text* + *output_routine_loc*);
          }
          print("->"); *token_show*(*p*); *end_diagnostic*(*false*);
        }
      }
    }
    else *loc* ← *p*;
  }

324.   When a token list has been fully scanned, the following computations should be done as we leave that level of input. The *token_type* tends to be equal to either *backed_up* or *inserted* about 2/3 of the time.

```
static void end_token_list(void)      ▷ leave a token-list input level ◁
{ if (token_type ≥ backed_up)       ▷ token list to be deleted ◁
  { if (token_type ≤ inserted) flush_list(start);
    else { delete_token_ref(start);      ▷ update reference count ◁
      if (token_type ≡ macro)       ▷ parameters must be flushed ◁
        while (param_ptr > param_start) { decr(param_ptr); flush_list(param_stack[param_ptr]);
        }
    }
  }
  else if (token_type ≡ u_template)
    if (align_state > 500000) align_state ← 0;
    else fatal_error("(interwoven␣alignment␣preambles␣are␣not␣allowed)");
  pop_input; check_interrupt;
}
```

325.   Sometimes TEX has read too far and wants to "unscan" what it has seen. The *back_input* procedure takes care of this by putting the token just scanned back into the input stream, ready to be read again. This procedure can be used only if *cur_tok* represents the token to be replaced. Some applications of TEX use this procedure a lot, so it has been slightly optimized for speed.

```
static void back_input(void)      ▷ undoes one token of input ◁
{ pointer p;      ▷ a token list of length one ◁
  while ((state ≡ token_list) ∧ (loc ≡ null) ∧ (token_type ≠ v_template)) end_token_list();
      ▷ conserve stack space ◁
  p ← get_avail(); info(p) ← cur_tok;
  if (cur_tok < right_brace_limit)
    if (cur_tok < left_brace_limit) decr(align_state);
    else incr(align_state);
  push_input; state ← token_list; start ← p; token_type ← backed_up; loc ← p;
    ▷ that was back_list(p), without procedure overhead ◁
}
```

326.   ⟨Insert token p into TEX's input 326⟩ ≡
```
{ t ← cur_tok; cur_tok ← p;
  if (a) { p ← get_avail(); info(p) ← cur_tok; link(p) ← loc; loc ← p; start ← p;
    if (cur_tok < right_brace_limit)
      if (cur_tok < left_brace_limit) decr(align_state);
      else incr(align_state);
  }
  else { back_input(); a ← eTeX_ex;
  }
  cur_tok ← t;
}
```
This code is used in section 282.

327.   The *back_error* routine is used when we want to replace an offending token just before issuing an error message. This routine, like *back_input*, requires that *cur_tok* has been set. We disable interrupts during the call of *back_input* so that the help message won't be lost.

> **static void** *back_error*(**void**)   ▷ back up one token and call *error* ◁
> { *OK_to_interrupt* ← *false*; *back_input*( ); *OK_to_interrupt* ← *true*; *error*( );
> }
>
> **static void** *ins_error*(**void**)   ▷ back up one inserted token and call *error* ◁
> { *OK_to_interrupt* ← *false*; *back_input*( ); *token_type* ← *inserted*; *OK_to_interrupt* ← *true*; *error*( );
> }

328.   The *begin_file_reading* procedure starts a new level of input for lines of characters to be read from a file, or as an insertion from the terminal. It does not take care of opening the file, nor does it set *loc* or *limit* or *line*.

> **static void** *begin_file_reading*(**void**)
> { **if** (*in_open* ≡ *max_in_open*) *overflow*("text␣input␣levels", *max_in_open*);
>   **if** (*first* ≡ *buf_size*) *overflow*("buffer␣size", *buf_size*);
>   *incr*(*in_open*); *push_input*; *index* ← *in_open*;
>   *source_filename_stack*[*index*] ← Λ;   ▷ TeX Live ◁
>   *full_source_filename_stack*[*index*] ← Λ;   ▷ TeX Live ◁
>   *eof_seen*[*index*] ← *false*; *grp_stack*[*index*] ← *cur_boundary*; *if_stack*[*index*] ← *cond_ptr*;
>   *line_stack*[*index*] ← *line*; *start* ← *first*; *state* ← *mid_line*; *name* ← 0;
>   ▷ *terminal_input* is now *true* ◁
> }

329.   Conversely, the variables must be downdated when such a level of input is finished:

> **static void** *end_file_reading*(**void**)
> { *first* ← *start*; *line* ← *line_stack*[*index*];
>   **if** ((*name* ≡ 18) ∨ (*name* ≡ 19)) *pseudo_close*( );
>   **else if** (*name* > 17) *a_close*(&*cur_file*);   ▷ forget it ◁
>   **if** (*full_source_filename_stack*[*in_open*] ≠ Λ) {
>   *free*(*full_source_filename_stack*[*in_open*]); *full_source_filename_stack*[*in_open*] ← Λ;
>   }
>   *pop_input*; *decr*(*in_open*);
> }

330.   In order to keep the stack from overflowing during a long sequence of inserted '\show' commands, the following routine removes completed error-inserted lines from memory.

> **static void** *clear_for_error_prompt*(**void**)
> { **while** ((*state* ≠ *token_list*) ∧ *terminal_input* ∧ (*input_ptr* > 0) ∧ (*loc* > *limit*)) *end_file_reading*( );
>   *print_ln*( ); *clear_terminal*;
> }

331.   To get TEX's whole input mechanism going, we perform the following actions.

⟨ Initialize the input routines 331 ⟩ ≡

    { *input_ptr* ← 0; *max_in_stack* ← 0; *in_open* ← 0; *open_parens* ← 0; *max_buf_stack* ← 0;
      grp_stack[0] ← 0; *if_stack*[0] ← *null*; *param_ptr* ← 0; *max_param_stack* ← 0; *first* ← *buf_size*;
      do {
         buffer[*first*] ← 0; *decr*(*first*);
      } **while** (¬(*first* ≡ 0));
      scanner_status ← *normal*; *warning_index* ← *null*; *first* ← 1; *state* ← *new_line*; *start* ← 1;
      index ← 0; *line* ← 0; *name* ← 0; *force_eof* ← *false*; *align_state* ← 1000000;
      if (¬*init_terminal*( )) *exit*(0);
      limit ← *last*; *first* ← *last* + 1;   ▷ *init_terminal* has set *loc* and *last* ◁
    }

This code is used in section 1337.

332.   Getting the next token.   The heart of TeX's input mechanism is the *get_next* procedure, which we shall develop in the next few sections of the program. Perhaps we shouldn't actually call it the "heart," however, because it really acts as TeX's eyes and mouth, reading the source files and gobbling them up. And it also helps TeX to regurgitate stored token lists that are to be processed again.

The main duty of *get_next* is to input one token and to set *cur_cmd* and *cur_chr* to that token's command code and modifier. Furthermore, if the input token is a control sequence, the *eqtb* location of that control sequence is stored in *cur_cs*; otherwise *cur_cs* is set to zero.

Underlying this simple description is a certain amount of complexity because of all the cases that need to be handled. However, the inner loop of *get_next* is reasonably short and fast.

When *get_next* is asked to get the next token of a \read line, it sets $cur\_cmd \equiv cur\_chr \equiv cur\_cs \equiv 0$ in the case that no more tokens appear on that line. (There might not be any tokens at all, if the *end_line_char* has *ignore* as its catcode.)

333.   The value of *par_loc* is the *eqtb* address of '\par'. This quantity is needed because a blank line of input is supposed to be exactly equivalent to the appearance of \par; we must set $cur\_cs{:} \leftarrow par\_loc$ when detecting a blank line.

The same is true for the input, for the warning message, since input is expected by default before every scanning and hence setting of *cur_cs*.

⟨ Global variables 13 ⟩ +≡
    static pointer *par_loc*;   ▷ location of '\par' in *eqtb* ◁
    static halfword *par_token*;   ▷ token representing '\par' ◁
    static pointer *input_loc*;   ▷ location of '\input' in *eqtb* ◁
    static halfword *input_token*;   ▷ token representing '\input' ◁

334.   ⟨ Put each of TeX's primitives into the hash table 226 ⟩ +≡
    primitive("**par**", *par_end*, 256);   ▷ cf. *scan_file_name* ◁
    $par\_loc \leftarrow cur\_val$; $par\_token \leftarrow cs\_token\_flag + par\_loc$;

335.   ⟨ Cases of *print_cmd_chr* for symbolic printing of primitives 227 ⟩ +≡
case *par_end*: *print_esc*("**par**"); **break**;

336.   Before getting into *get_next*, let's consider the subroutine that is called when an '\outer' control sequence has been scanned or when the end of a file has been reached. These two cases are distinguished by *cur_cs*, which is zero at the end of a file.

```
static void check_outer_validity(void)
{ pointer p;        ▷ points to inserted token list ◁
  pointer q;        ▷ auxiliary pointer ◁
  if (scanner_status ≠ normal) { deletions_allowed ← false;
    ⟨Back up an outer control sequence so that it can be reread 337⟩;
    if (scanner_status > skipping) ⟨Tell the user what has run away and try to recover 338⟩
    else { print_err("Incomplete␣"); print_cmd_chr(if_test, cur_if);
      print(";␣all␣text␣was␣ignored␣after␣line␣"); print_int(skip_line);
      help3("A␣forbidden␣control␣sequence␣occurred␣in␣skipped␣text.",
      "This␣kind␣of␣error␣happens␣when␣you␣say␣'\\if...'␣and␣forget",
      "the␣matching␣'\\fi'.␣I've␣inserted␣a␣'\\fi';␣this␣might␣work.");
      if (cur_cs ≠ 0) cur_cs ← 0;
      else help_line[2] ← "The␣file␣ended␣while␣I␣was␣skipping␣conditional␣text.";
      cur_tok ← cs_token_flag + frozen_fi; ins_error();
    }
    deletions_allowed ← true;
  }
}
```

337.   An outer control sequence that occurs in a \read will not be reread, since the error recovery for \read is not very powerful.

⟨Back up an outer control sequence so that it can be reread 337⟩ ≡
```
  if (cur_cs ≠ 0) { if ((state ≡ token_list) ∨ (name < 1) ∨ (name > 17)) { p ← get_avail();
      info(p) ← cs_token_flag + cur_cs; back_list(p);     ▷ prepare to read the control sequence again ◁
    }
    cur_cmd ← spacer; cur_chr ← '␣';     ▷ replace it by a space ◁
  }
```
This code is used in section 336.

338.   ⟨Tell the user what has run away and try to recover 338⟩ ≡
```
  { runaway();     ▷ print a definition, argument, or preamble ◁
    if (cur_cs ≡ 0) print_err("File␣ended");
    else { cur_cs ← 0; print_err("Forbidden␣control␣sequence␣found");
    }
    print("␣while␣scanning␣"); ⟨Print either 'definition' or 'use' or 'preamble' or 'text', and insert
        tokens that should lead to recovery 339⟩;
    print("␣of␣"); sprint_cs(warning_index);
    help4("I␣suspect␣you␣have␣forgotten␣a␣'}',␣causing␣me",
    "to␣read␣past␣where␣you␣wanted␣me␣to␣stop.",
    "I'll␣try␣to␣recover;␣but␣if␣the␣error␣is␣serious,",
    "you'd␣better␣type␣'E'␣or␣'X'␣now␣and␣fix␣your␣file.");
    error();
  }
```
This code is used in section 336.

339.   The recovery procedure can't be fully understood without knowing more about the TEX routines that should be aborted, but we can sketch the ideas here: For a runaway definition or a runaway balanced text we will insert a right brace; for a runaway preamble, we will insert a special `\cr` token and a right brace; and for a runaway argument, we will set *long_state* to *outer_call* and insert `\par`.

⟨Print either 'definition' or 'use' or 'preamble' or 'text', and insert tokens that should lead to
     recovery 339⟩ ≡
  $p \leftarrow get\_avail(\,)$;
  switch (*scanner_status*) {
  case *defining*:
     { *print*("definition"); $info(p) \leftarrow right_brace_token + $'}';
     } **break**;
  case *matching*:
     { *print*("use"); $info(p) \leftarrow par\_token$; $long\_state \leftarrow outer\_call$;
     } **break**;
  case *aligning*:
     { *print*("preamble"); $info(p) \leftarrow right_brace_token + $'}'; $q \leftarrow p$; $p \leftarrow get\_avail(\,)$; $link(p) \leftarrow q$;
       $info(p) \leftarrow cs\_token\_flag + frozen\_cr$; $align\_state \leftarrow -1000000$;
     } **break**;
  case *absorbing*:
     { *print*("text"); $info(p) \leftarrow right_brace_token + $'}';
     }
  }   ▷ there are no other cases ◁
  $ins\_list(p)$
This code is used in section 338.

340.   We need to mention a procedure here that may be called by *get_next*.

  static void *firm_up_the_line*(**void**);

341.   Now we're ready to take the plunge into *get_next* itself. Parts of this routine are executed more often than any other instructions of TEX.

  static void *get_next*(**void**)   ▷ sets *cur_cmd*, *cur_chr*, *cur_cs* to next token ◁
  {   ▷ go here to get the next input token ◁   ▷ go here to eat the next character from a file ◁
     ▷ go here to digest it again ◁   ▷ go here to start looking for a control sequence ◁   ▷ go here when a
       control sequence has been found ◁   ▷ go here when the next input token has been got ◁
    int k;   ▷ an index into *buffer* ◁
    halfword t;   ▷ a token ◁
    int *cat*;   ▷ *cat_code*(*cur_chr*), usually ◁
    ASCII_code c, cc;   ▷ constituents of a possible expanded code ◁
    int d;   ▷ number of excess characters in an expanded code ◁
  restart: $cur\_cs \leftarrow 0$;
    if (*state* $\neq$ *token_list*) ⟨Input from external file, **goto** *restart* if no input found 343⟩
    else ⟨Input from token list, **goto** *restart* if end of list or if a parameter needs to be expanded 357⟩;
    ⟨If an alignment entry has just ended, take appropriate action 342⟩;
  }

342. An alignment entry ends when a tab or \cr occurs, provided that the current level of braces is the same as the level that was present at the beginning of that alignment entry; i.e., provided that *align_state* has returned to the value it had after the ⟨u_j⟩ template for that entry.

⟨If an alignment entry has just ended, take appropriate action 342⟩ ≡
   if (*cur_cmd* ≤ *car_ret*)
     if (*cur_cmd* ≥ *tab_mark*)
       if (*align_state* ≡ 0) ⟨Insert the ⟨v_j⟩ template and **goto** *restart* 789⟩

This code is used in section 341.

343. ⟨Input from external file, **goto** *restart* if no input found 343⟩ ≡
   { *get_cur_chr*:
    if (*loc* ≤ *limit*)   ▷ current line not yet finished ◁
    { *cur_chr* ← *buffer*[*loc*]; *incr*(*loc*);
    reswitch: *cur_cmd* ← *cat_code*(*cur_chr*); ⟨Change state if necessary, and **goto switch** if the current
         character should be ignored, or **goto** *reswitch* if the current character changes to another 344⟩;
    }
    else { *state* ← *new_line*;
     ⟨Move to next line of file, or **goto** *restart* if there is no next line, or **return** if a \read line has
       finished 360⟩;
     check_interrupt; **goto** *get_cur_chr*;
    }
   }

This code is used in section 341.

344. The following 48-way switch accomplishes the scanning quickly, assuming that a decent Pascal compiler has translated the code. Note that the numeric values for *mid_line*, *skip_blanks*, and *new_line* are spaced apart from each other by *max_char_code* + 1, so we can add a character's command code to the state to get a single number that characterizes both.

#**define** *any_state_plus*(*A*) **case** *mid_line* + *A*: **case** *skip_blanks* + *A*: **case** *new_line* + *A*

⟨Change state if necessary, and **goto switch** if the current character should be ignored, or **goto** *reswitch* if
     the current character changes to another 344⟩ ≡
   switch (*state* + *cur_cmd*) {
   ⟨Cases where character is ignored 345⟩: **goto** *get_cur_chr*;
   any_state_plus(*escape*): ⟨Scan a control sequence and set *state*: ← *skip_blanks* or *mid_line* 354⟩ **break**;
   any_state_plus(*active_char*):
     ⟨Process an active-character control sequence and set *state*: ← *mid_line* 353⟩ **break**;
   any_state_plus(*sup_mark*): ⟨If this *sup_mark* starts an expanded character like ^^A or ^^df, then **goto**
     reswitch, otherwise set *state*: ← *mid_line* 352⟩ **break**;
   any_state_plus(*invalid_char*): ⟨Decry the invalid character and **goto** *restart* 346⟩
   ⟨Handle situations involving spaces, braces, changes of state 347⟩
   default: *do_nothing*;
   }

This code is used in section 343.

345. ⟨Cases where character is ignored 345⟩ ≡
   any_state_plus(*ignore*): **case** *skip_blanks* + *spacer*: **case** *new_line* + *spacer*

This code is used in section 344.

346.   We go to *restart* instead of to *get_cur_chr*, because *state* might equal *token_list* after the error has been dealt with (cf. *clear_for_error_prompt*).

⟨Decry the invalid character and **goto** *restart* 346⟩ ≡
  { *print_err*("Text␣line␣contains␣an␣invalid␣character");
    help2("A␣funny␣symbol␣that␣I␣can't␣read␣has␣just␣been␣input.",
    "Continue,␣and␣I'll␣forget␣that␣it␣ever␣happened.");
    deletions_allowed ← *false*; *error*( ); *deletions_allowed* ← *true*; **goto** *restart*;
  }

This code is used in section 344.

347.   #**define** *add_delims_to*(A) A + *math_shift*: A + *tab_mark*: A + *mac_param*: A + *sub_mark*:
      A + *letter*: A + *other_char*

⟨Handle situations involving spaces, braces, changes of state 347⟩ ≡
case *mid_line* + *spacer*: ⟨Enter *skip_blanks* state, emit a space 349⟩ **break**;
case *mid_line* + *car_ret*: ⟨Finish line, emit a space 348⟩ **break**;
case *skip_blanks* + *car_ret*: *any_state_plus*(*comment*): ⟨Finish line, **goto switch** 350⟩
case *new_line* + *car_ret*: ⟨Finish line, emit a \par 351⟩ **break**;
case *mid_line* + *left_brace*: *incr*(*align_state*); **break**;
case *skip_blanks* + *left_brace*: **case** *new_line* + *left_brace*:
  { *state* ← *mid_line*; *incr*(*align_state*);
  } **break**;
case *mid_line* + *right_brace*: *decr*(*align_state*); **break**;
case *skip_blanks* + *right_brace*: **case** *new_line* + *right_brace*:
  { *state* ← *mid_line*; *decr*(*align_state*);
  } **break**;
add_delims_to(**case** *skip_blanks*): *add_delims_to*(**case** *new_line*): *state* ← *mid_line*; **break**;

This code is used in section 344.

348.   When a character of type *spacer* gets through, its character code is changed to "␣" = 040. This means that the ASCII codes for tab and space, and for the space inserted at the end of a line, will be treated alike when macro parameters are being matched. We do this since such characters are indistinguishable on most computer terminal displays.

⟨Finish line, emit a space 348⟩ ≡
  { *loc* ← *limit* + 1; *cur_cmd* ← *spacer*; *cur_chr* ← '␣';
  }

This code is used in section 347.

349.   The following code is performed only when *cur_cmd* ≡ *spacer*.

⟨Enter *skip_blanks* state, emit a space 349⟩ ≡
  { *state* ← *skip_blanks*; *cur_chr* ← '␣';
  }

This code is used in section 347.

350.   ⟨Finish line, **goto switch** 350⟩ ≡
  { *loc* ← *limit* + 1; **goto** *get_cur_chr*;
  }

This code is used in section 347.

351. ⟨Finish line, emit a `\par` 351⟩ ≡
  { $loc \leftarrow limit + 1$; $cur\_cs \leftarrow par\_loc$; $cur\_cmd \leftarrow eq\_type(cur\_cs)$; $cur\_chr \leftarrow equiv(cur\_cs)$;
    if ($cur\_cmd \geq outer\_call$) $check\_outer\_validity(\,)$;
  }

This code is used in section 347.

352.   Notice that a code like `^^8` becomes `x` if not followed by a hex digit.

#**define** $is\_hex(A)$ $(((A \geq \text{'0'}) \wedge (A \leq \text{'9'})) \vee ((A \geq \text{'a'}) \wedge (A \leq \text{'f'})))$
#**define** $hex\_to\_cur\_chr$
        if ($c \leq \text{'9'}$) $cur\_chr \leftarrow c - \text{'0'}$; **else** $cur\_chr \leftarrow c - \text{'a'} + 10$;
        if ($cc \leq \text{'9'}$) $cur\_chr \leftarrow 16 * cur\_chr + cc - \text{'0'}$;
        else $cur\_chr \leftarrow 16 * cur\_chr + cc - \text{'a'} + 10$

⟨If this sup_mark starts an expanded character like `^^A` or `^^df`, then **goto** $reswitch$, otherwise set $state$:
        $\leftarrow mid\_line$ 352⟩ ≡
  { **if** ($cur\_chr \equiv buffer[loc]$)
      if ($loc < limit$) { $c \leftarrow buffer[loc + 1]$; **if** ($c < °200$)   ▷ yes we have an expanded char ◁
        { $loc \leftarrow loc + 2$;
          if ($is\_hex(c)$)
            if ($loc \leq limit$) { $cc \leftarrow buffer[loc]$; **if** ($is\_hex(cc)$) { $incr(loc)$; $hex\_to\_cur\_chr$;
                goto $reswitch$;
              }
            }
          if ($c < °100$) $cur\_chr \leftarrow c + °100$; **else** $cur\_chr \leftarrow c - °100$;
          goto $reswitch$;
        }
      }
    $state \leftarrow mid\_line$;
  }

This code is used in section 344.

353. ⟨Process an active-character control sequence and set $state$: $\leftarrow mid\_line$ 353⟩ ≡
  { $cur\_cs \leftarrow cur\_chr + active\_base$; $cur\_cmd \leftarrow eq\_type(cur\_cs)$; $cur\_chr \leftarrow equiv(cur\_cs)$;
    $state \leftarrow mid\_line$;
    if ($cur\_cmd \geq outer\_call$) $check\_outer\_validity(\,)$;
  }

This code is used in section 344.

354. Control sequence names are scanned only when they appear in some line of a file; once they have been scanned the first time, their *eqtb* location serves as a unique identification, so TeX doesn't need to refer to the original name any more except when it prints the equivalent in symbolic form.

The program that scans a control sequence has been written carefully in order to avoid the blowups that might otherwise occur if a malicious user tried something like '\catcode´15=0'. The algorithm might look at *buffer*[*limit* + 1], but it never looks at *buffer*[*limit* + 2].

If expanded characters like '^^A' or '^^df' appear in or just following a control sequence name, they are converted to single characters in the buffer and the process is repeated, slowly but surely.

⟨Scan a control sequence and set *state*: ← *skip_blanks* or *mid_line* 354⟩ ≡
  { **if** (*loc* > *limit*) *cur_cs* ← *null_cs*;   ▷ *state* is irrelevant in this case ◁
    else { *start_cs*: *k* ← *loc*; *cur_chr* ← *buffer*[*k*]; *cat* ← *cat_code*(*cur_chr*); *incr*(*k*);
      if (*cat* ≡ *letter*) *state* ← *skip_blanks*;
      else if (*cat* ≡ *spacer*) *state* ← *skip_blanks*;
      else *state* ← *mid_line*;

           code is encountered, reduce it and **goto** *start_cs*; otherwise if a multiletter control sequence
           is found, adjust *cur_cs* and *loc*, and **goto** *found* 356⟩
      else ⟨If an expanded code is present, reduce it and **goto** *start_cs* 355⟩;
      cur_cs ← *single_base* + *buffer*[*loc*]; *incr*(*loc*);
    }
  found: *cur_cmd* ← *eq_type*(*cur_cs*); *cur_chr* ← *equiv*(*cur_cs*);
    if (*cur_cmd* ≥ *outer_call*) *check_outer_validity*( );
  }

This code is used in section 344.

355. Whenever we reach the following piece of code, we will have *cur_chr* ≡ *buffer*[*k* − 1] and *k* ≤ *limit* + 1 and *cat* ≡ *cat_code*(*cur_chr*). If an expanded code like ^^A or ^^df appears in *buffer*[(*k* − 1) .. (*k* + 1)] or *buffer*[(*k* − 1) .. (*k* + 2)], we will store the corresponding code in *buffer*[*k* − 1] and shift the rest of the buffer left two or three places.

⟨If an expanded code is present, reduce it and **goto** *start_cs* 355⟩ ≡
  { **if** (*buffer*[*k*] ≡ *cur_chr*) **if** (*cat* ≡ *sup_mark*) **if** (*k* < *limit*) { *c* ← *buffer*[*k* + 1]; **if** (*c* < °*200*)
      ▷ yes, one is indeed present ◁
    { *d* ← 2;
      if (*is_hex*(*c*)) **if** (*k* + 2 ≤ *limit*) { *cc* ← *buffer*[*k* + 2]; **if** (*is_hex*(*cc*)) *incr*(*d*);
        }
      if (*d* > 2) { *hex_to_cur_chr*; *buffer*[*k* − 1] ← *cur_chr*;
      }
      else if (*c* < °*100*) *buffer*[*k* − 1] ← *c* + °*100*;
      else *buffer*[*k* − 1] ← *c* − °*100*;
      limit ← *limit* − *d*; *first* ← *first* − *d*;
      while (*k* ≤ *limit*) { *buffer*[*k*] ← *buffer*[*k* + *d*]; *incr*(*k*);
      }
      goto *start_cs*;
    }
    }
  }

This code is used in sections 354 and 356.

356. ⟨Scan ahead in the buffer until finding a nonletter; if an expanded code is encountered, reduce it and **goto** *start_cs*; otherwise if a multiletter control sequence is found, adjust *cur_cs* and *loc*, and **goto** *found* 356⟩ ≡

{ **do** {
    cur_chr ← *buffer*[*k*]; *cat* ← *cat_code*(*cur_chr*); *incr*(*k*);
  } **while** (¬((*cat* ≠ *letter*) ∨ (*k* > *limit*)));
  ⟨If an expanded code is present, reduce it and **goto** *start_cs* 355⟩;
  if (*cat* ≠ *letter*) *decr*(*k*);   ▷ now *k* points to first nonletter ◁
  if (*k* > *loc* + 1)   ▷ multiletter control sequence has been scanned ◁
  { *cur_cs* ← *id_lookup*(*loc*, *k* − *loc*); *loc* ← *k*; **goto** *found*;
  }
}

This code is used in section 354.

357. Let's consider now what happens when *get_next* is looking at a token list.

⟨Input from token list, **goto** *restart* if end of list or if a parameter needs to be expanded 357⟩ ≡

  if (*loc* ≠ *null*)   ▷ list not exhausted ◁
  { *t* ← *info*(*loc*); *loc* ← *link*(*loc*);   ▷ move to next ◁
    if (*t* ≥ *cs_token_flag*)   ▷ a control sequence token ◁
    { *cur_cs* ← *t* − *cs_token_flag*; *cur_cmd* ← *eq_type*(*cur_cs*); *cur_chr* ← *equiv*(*cur_cs*);
      if (*cur_cmd* ≥ *outer_call*)
        if (*cur_cmd* ≡ *dont_expand*) ⟨Get the next token, suppressing expansion 358⟩
        else *check_outer_validity*();
    }
    else { *cur_cmd* ← *t*/°400; *cur_chr* ← *t* % °400;
      switch (*cur_cmd*) {
      case *left_brace*: *incr*(*align_state*); **break**;
      case *right_brace*: *decr*(*align_state*); **break**;
      case *out_param*: ⟨Insert macro parameter and **goto** *restart* 359⟩
      default: *do_nothing*;
      }
    }
  }
  else {   ▷ we are done with this token list ◁
    end_token_list(); **goto** *restart*;   ▷ resume previous level ◁
  }

This code is used in section 341.

358. The present point in the program is reached only when the *expand* routine has inserted a special marker into the input. In this special case, *info*(*loc*) is known to be a control sequence token, and *link*(*loc*) ≡ *null*.

#**define** *no_expand_flag* 257   ▷ this characterizes a special variant of *relax* ◁

⟨Get the next token, suppressing expansion 358⟩ ≡

  { *cur_cs* ← *info*(*loc*) − *cs_token_flag*; *loc* ← *null*;
    cur_cmd ← *eq_type*(*cur_cs*); *cur_chr* ← *equiv*(*cur_cs*);
    if (*cur_cmd* > *max_command*) { *cur_cmd* ← *relax*; *cur_chr* ← *no_expand_flag*;
    }
  }

This code is used in section 357.

359. ⟨Insert macro parameter and **goto** *restart* 359⟩ ≡
  { *begin_token_list*(*param_stack*[*param_start* + *cur_chr* − 1], *parameter*); **goto** *restart*;
  }

This code is used in section 357.

360.   All of the easy branches of *get_next* have now been taken care of. There is one more branch.

#**define** *end_line_char_inactive*   (*end_line_char* < 0) ∨ (*end_line_char* > 255)

⟨Move to next line of file, or **goto** *restart* if there is no next line, or **return** if a \read line has
       finished 360⟩ ≡
  if (*name* > 17) ⟨Read next line of file into *buffer*, or **goto** *restart* if the file has ended 362⟩
  else { **if** (¬*terminal_input*)   ▷ \read line has ended ◁
    { *cur_cmd* ← 0; *cur_chr* ← 0; **return**;
    }
    if (*input_ptr* > 0)   ▷ text was inserted during error recovery ◁
    { *end_file_reading*(); **goto** *restart*;   ▷ resume previous level ◁
    }
    if (*selector* < *log_only*) *open_log_file*();
    if (*interaction* > *nonstop_mode*) { **if** (*end_line_char_inactive*) *incr*(*limit*);
      if (*limit* ≡ *start*)   ▷ previous line was empty ◁
        print_nl("(Please␣type␣a␣command␣or␣say␣'\\end')");
      print_ln(); *first* ← *start*; *prompt_input*("*");   ▷ input on-line into *buffer* ◁
      limit ← *last*;
      if (*end_line_char_inactive*) *decr*(*limit*);
      else *buffer*[*limit*] ← *end_line_char*;
      first ← *limit* + 1; *loc* ← *start*;
    }
    else *fatal_error*("***␣(job␣aborted,␣no␣legal␣\\end␣found)");
        ▷ nonstop mode, which is intended for overnight batch processing, never waits for on-line input ◁
  }

This code is used in section 343.

361.   The global variable *force_eof* is normally *false*; it is set *true* by an \endinput command.

⟨Global variables 13⟩ +≡
  static bool *force_eof*;   ▷ should the next \input be aborted early? ◁

362. ⟨ Read next line of file into *buffer*, or **goto** *restart* if the file has ended 362 ⟩ ≡

      }
    if (*force_eof*) { **if** (*tracing_nesting* > 0)
        if ((*grp_stack*[*in_open*] ≠ *cur_boundary*) ∨ (*if_stack*[*in_open*] ≠ *cond_ptr*)) *file_warning*();
            ▷ give warning for some unfinished groups and/or conditionals ◁
      if (*name* ≥ 19) { *print_char*(')'); *decr*(*open_parens*); *update_terminal*;
          ▷ show user that file has been read ◁
      }
      force_eof ← *false*; *end_file_reading*();   ▷ resume previous level ◁
      check_outer_validity(); **goto** *restart*;
    }
    if (*end_line_char_inactive*) *decr*(*limit*);
    else *buffer*[*limit*] ← *end_line_char*;
    first ← *limit* + 1; *loc* ← *start*;   ▷ ready to read ◁
  }
This code is used in section 360.

363. If the user has set the *pausing* parameter to some positive value, and if nonstop mode has not been selected, each line of input is displayed on the terminal and the transcript file, followed by '=>'. TeX waits for a response. If the response is simply *carriage_return*, the line is accepted as it stands, otherwise the line typed is used instead of the line in the file.

> **static void** *firm_up_the_line*(**void**)
> { **int** k;   ▷ an index into *buffer* ◁
>
>   *limit* ← *last*;
>   **if** (*pausing* > 0)
>   **if** (*interaction* > *nonstop_mode*) { *wake_up_terminal*; *print_ln*( );
>   **if** (*start* < *limit*)
>   **for** (k ← *start*; k ≤ *limit* − 1; k++) *printn*(*buffer*[k]);
>   *first* ← *limit*; *prompt_input*("=>");   ▷ wait for user response ◁
>   **if** (*last* > *first*) { **for** (k ← *first*; k ≤ *last* − 1; k++)   ▷ move line down in buffer ◁
>   *buffer*[k + *start* − *first*] ← *buffer*[k];
>   *limit* ← *start* + *last* − *first*;
>   }
>   }
> }

364. Since *get_next* is used so frequently in TeX, it is convenient to define three related procedures that do a little more:

get_token not only sets *cur_cmd* and *cur_chr*, it also sets *cur_tok*, a packed halfword version of the current token.

get_x_token, meaning "get an expanded token," is like *get_token*, but if the current token turns out to be a user-defined control sequence (i.e., a macro call), or a conditional, or something like \topmark or \expandafter or \csname, it is eliminated from the input by beginning the expansion of the macro or the evaluation of the conditional.

x_token is like *get_x_token* except that it assumes that *get_next* has already been called.

In fact, these three procedures account for almost every use of *get_next*.

365. No new control sequences will be defined except during a call of *get_token*, or when \csname compresses a token list, because *no_new_control_sequence* is always *true* at other times.

> **static void** *get_token*(**void**)   ▷ sets *cur_cmd*, *cur_chr*, *cur_tok* ◁
> { *no_new_control_sequence* ← *false*; *get_next*( ); *no_new_control_sequence* ← *true*;
>   **if** (*cur_cs* ≡ 0) *cur_tok* ← (*cur_cmd* ∗ °*400*) + *cur_chr*;
>   **else** *cur_tok* ← *cs_token_flag* + *cur_cs*;
> }

366. Expanding the next token.   Only a dozen or so command codes $> max\_command$ can possibly be returned by *get_next*; in increasing order, they are *undefined_cs*, *expand_after*, *no_expand*, *input*, *if_test*, *fi_or_else*, *cs_name*, *convert*, *the*, *top_bot_mark*, *call*, *long_call*, *outer_call*, *long_outer_call*, and *end_template*.

The *expand* subroutine is used when $cur\_cmd > max\_command$. It removes a "call" or a conditional or one of the other special operations just listed. It follows that *expand* might invoke itself recursively. In all cases, *expand* destroys the current token, but it sets things up so that the next *get_next* will deliver the appropriate next token. The value of *cur_tok* need not be known when *expand* is called.

Since several of the basic scanning routines communicate via global variables, their values are saved as local variables of *expand* so that recursive calls don't invalidate them.

⟨ Declare the procedure called *macro_call* 389 ⟩

    $buffer[j] \leftarrow info(p) \% °400$; $incr(j)$; $p \leftarrow link(p)$;
  }
  if $(j \equiv first)$ $cur\_cs \leftarrow null\_cs$;   ▷ the list is empty ◁
  else if $(j > first + 1)$ { $no\_new\_control\_sequence \leftarrow false$; $cur\_cs \leftarrow id\_lookup(first, j - first)$;
    $no\_new\_control\_sequence \leftarrow true$;
  }
  else $cur\_cs \leftarrow single\_base + buffer[first]$ ▷ the list has length one ◁
This code is used in section 372.

375.   An $end\_template$ command is effectively changed to an $endv$ command by the following code. (The reason for this is discussed below; the $frozen\_end\_template$ at the end of the template has passed the $check\_outer\_validity$ test, so its mission of error detection has been accomplished.)

⟨Insert a token containing $frozen\_endv$ 375⟩ ≡
  { $cur\_tok \leftarrow cs\_token\_flag + frozen\_endv$; $back\_input()$;
  }
This code is used in section 366.

376.   The processing of \input involves the $start\_input$ subroutine, which will be declared later; the processing of \endinput is trivial.

⟨Put each of TEX's primitives into the hash table 226⟩ +≡
  $primitive($"input"$, input, 0)$;
  $input\_loc \leftarrow cur\_val$; $input\_token \leftarrow cs\_token\_flag + input\_loc$; $primitive($"endinput"$, input, 1)$;

377.   ⟨Cases of $print\_cmd\_chr$ for symbolic printing of primitives 227⟩ +≡
case $input$:
  if $(chr\_code \equiv 0)$ $print\_esc($"input"$)$;
  else ⟨Cases of $input$ for $print\_cmd\_chr$ 1432⟩
  else $print\_esc($"endinput"$)$; **break**;

378.   ⟨Initiate or terminate input from a file 378⟩ ≡
  if $(cur\_chr \equiv 1)$ $force\_eof \leftarrow true$;
  else ⟨Cases for $input$ 1433⟩
  else
    if $(name\_in\_progress)$ $insert\_relax()$;
    else $start\_input()$;
This code is used in section 367.

379.   Sometimes the expansion looks too far ahead, so we want to insert a harmless \relax into the user's input.

⟨Declare the procedure called $insert\_relax$ 379⟩ ≡
  static void $insert\_relax($**void**$)$
  { $cur\_tok \leftarrow cs\_token\_flag + cur\_cs$; $back\_input()$; $cur\_tok \leftarrow cs\_token\_flag + frozen\_relax$;
    $back\_input()$; $token\_type \leftarrow inserted$;
  }
This code is used in section 366.

380.   Here is a recursive procedure that is T$_E$X's usual way to get the next token of input. It has been slightly optimized to take account of common cases.

```
static void get_x_token(void)        ▷ sets cur_cmd, cur_chr, cur_tok, and expands macros ◁
{ restart: get_next( );
  if (cur_cmd ≤ max_command) goto done;
  if (cur_cmd ≥ call)
    if (cur_cmd < end_template) macro_call( );
    else { cur_cs ← frozen_endv; cur_cmd ← endv; goto done;        ▷ cur_chr ≡ null_list ◁
    }
  else expand( );
  goto restart;
done:
  if (cur_cs ≡ 0) cur_tok ← (cur_cmd ∗ °400) + cur_chr;
  else cur_tok ← cs_token_flag + cur_cs;
}
```

381.   The *get_x_token* procedure is essentially equivalent to two consecutive procedure calls: *get_next*; *x_token*.

```
static void x_token(void)      ▷ get_x_token without the initial get_next ◁
{ while (cur_cmd > max_command) { expand( ); get_next( );
  }
  if (cur_cs ≡ 0) cur_tok ← (cur_cmd ∗ °400) + cur_chr;
  else cur_tok ← cs_token_flag + cur_cs;
}
```

382.   A control sequence that has been \def'ed by the user is expanded by T$_E$X's *macro_call* procedure.

Before we get into the details of *macro_call*, however, let's consider the treatment of primitives like \topmark, since they are essentially macros without parameters. The token lists for such marks are kept in a global array of five pointers; we refer to the individual entries of this array by symbolic names *top_mark*, etc. The value of *top_mark* is either *null* or a pointer to the reference count of a token list.

```
#define marks_code  5     ▷ add this for \topmarks etc. ◁
```

```
#define top_mark_code  0      ▷ the mark in effect at the previous page break ◁
#define first_mark_code  1       ▷ the first mark between top_mark and bot_mark ◁
#define bot_mark_code  2      ▷ the mark in effect at the current page break ◁
#define split_first_mark_code  3      ▷ the first mark found by \vsplit ◁
#define split_bot_mark_code  4      ▷ the last mark found by \vsplit ◁
#define top_mark   cur_mark[top_mark_code]
#define first_mark   cur_mark[first_mark_code]
#define bot_mark   cur_mark[bot_mark_code]
#define split_first_mark   cur_mark[split_first_mark_code]
#define split_bot_mark   cur_mark[split_bot_mark_code]
```

⟨Global variables 13⟩ +≡
```
static pointer cur_mark0[split_bot_mark_code − top_mark_code + 1],
    ∗const cur_mark ← cur_mark0 − top_mark_code;       ▷ token lists for marks ◁
```

383.   ⟨Set initial values of key variables 21⟩ +≡
```
top_mark ← null; first_mark ← null; bot_mark ← null; split_first_mark ← null;
split_bot_mark ← null;
```

384.   ⟨Put each of TₑX's primitives into the hash table 226⟩ +≡
  primitive("topmark", *top_bot_mark*, *top_mark_code*);
  primitive("firstmark", *top_bot_mark*, *first_mark_code*);
  primitive("botmark", *top_bot_mark*, *bot_mark_code*);
  primitive("splitfirstmark", *top_bot_mark*, *split_first_mark_code*);
  primitive("splitbotmark", *top_bot_mark*, *split_bot_mark_code*);

385.   ⟨Cases of *print_cmd_chr* for symbolic printing of primitives 227⟩ +≡
case *top_bot_mark*:
  { **switch** ((*chr_code* % *marks_code*)) {
    case *first_mark_code*: *print_esc*("firstmark"); **break**;
    case *bot_mark_code*: *print_esc*("botmark"); **break**;
    case *split_first_mark_code*: *print_esc*("splitfirstmark"); **break**;
    case *split_bot_mark_code*: *print_esc*("splitbotmark"); **break**;
    default: *print_esc*("topmark");
    }
    if (*chr_code* ≥ *marks_code*) *print_char*('s');
  } **break**;

386.   The following code is activated when *cur_cmd* ≡ *top_bot_mark* and when *cur_chr* is a code like
top_mark_code.

⟨Insert the appropriate mark text into the scanner 386⟩ ≡
  { *t* ← *cur_chr* % *marks_code*;
    if (*cur_chr* ≥ *marks_code*) *scan_register_num*( ); **else** *cur_val* ← 0;
    if (*cur_val* ≡ 0) *cur_ptr* ← *cur_mark*[*t*];
    else ⟨Compute the mark pointer for mark type *t* and class *cur_val* 1508⟩;
    if (*cur_ptr* ≠ *null*) *begin_token_list*(*cur_ptr*, *mark_text*);
  }
This code is used in section 367.

387.   Now let's consider *macro_call* itself, which is invoked when TₑX is scanning a control sequence whose
cur_cmd is either *call*, *long_call*, *outer_call*, or *long_outer_call*. The control sequence definition appears in
the token list whose reference count is in location *cur_chr* of *mem*.
    The global variable *long_state* will be set to *call* or to *long_call*, depending on whether or not the control
sequence disallows \par in its parameters. The *get_next* routine will set *long_state* to *outer_call* and emit
\par, if a file ends or if an \outer control sequence occurs in the midst of an argument.
⟨Global variables 13⟩ +≡
  static int *long_state*;   ▷ governs the acceptance of \par ◁

388.   The parameters, if any, must be scanned before the macro is expanded. Parameters are token lists
without reference counts. They are placed on an auxiliary stack called *pstack* while they are being scanned,
since the *param_stack* may be losing entries during the matching process. (Note that *param_stack* can't
be gaining entries, since *macro_call* is the only routine that puts anything onto *param_stack*, and it is not
recursive.)
⟨Global variables 13⟩ +≡
  static pointer *pstack*[9];   ▷ arguments supplied to a macro ◁

389. After parameter scanning is complete, the parameters are moved to the *param_stack*. Then the macro body is fed to the scanner; in other words, *macro_call* places the defined text of the control sequence at the top of TEX's input stack, so that *get_next* will proceed to read it next.

The global variable *cur_cs* contains the *eqtb* address of the control sequence being expanded, when *macro_call* begins. If this control sequence has not been declared \long, i.e., if its command code in the *eq_type* field is not *long_call* or *long_outer_call*, its parameters are not allowed to contain the control sequence \par. If an illegal \par appears, the macro call is aborted, and the \par will be rescanned.

⟨ Declare the procedure called *macro_call* 389 ⟩ ≡
  static void *macro_call*(**void**)   ▷ invokes a user-defined control sequence ◁
  { **pointer** *r*;   ▷ current node in the macro's token list ◁
    pointer *p*;   ▷ current node in parameter token list being built ◁
    pointer *q*;   ▷ new node being put into the token list ◁
    pointer *s*;   ▷ backup pointer for parameter matching ◁
    pointer *t*;   ▷ cycle pointer for backup recovery ◁
    pointer *u, v*;   ▷ auxiliary pointers for backup recovery ◁
    pointer *rbrace_ptr*;   ▷ one step before the last *right_brace* token ◁
    small_number *n*;   ▷ the number of parameters scanned ◁
    halfword *unbalance*;   ▷ unmatched left braces in current parameter ◁
    int *m*;   ▷ the number of tokens or groups (usually) ◁
    pointer *ref_count*;   ▷ start of the token list ◁
    small_number *save_scanner_status*;   ▷ *scanner_status* upon entry ◁
    pointer *save_warning_index*;   ▷ *warning_index* upon entry ◁
    ASCII_code *match_chr*;   ▷ character used in parameter ◁

    save_scanner_status ← *scanner_status*; *save_warning_index* ← *warning_index*;
    warning_index ← *cur_cs*; *ref_count* ← *cur_chr*; *r* ← *link*(*ref_count*); *n* ← 0;
    if (*tracing_macros* > 0) ⟨ Show the text of the macro being expanded 401 ⟩;
    if (*info*(*r*) ≡ *protected_token*) *r* ← *link*(*r*);
    if (*info*(*r*) ≠ *end_match_token*) ⟨ Scan the parameters and make *link*(*r*) point to the macro body; but
        return if an illegal \par is detected 391 ⟩;
    ⟨ Feed the macro body and its parameters to the scanner 390 ⟩;
  end: *scanner_status* ← *save_scanner_status*; *warning_index* ← *save_warning_index*;
  }

This code is used in section 366.

390. Before we put a new token list on the input stack, it is wise to clean off all token lists that have recently been depleted. Then a user macro that ends with a call to itself will not require unbounded stack space.

⟨ Feed the macro body and its parameters to the scanner 390 ⟩ ≡
  while ((*state* ≡ *token_list*) ∧ (*loc* ≡ *null*) ∧ (*token_type* ≠ *v_template*)) *end_token_list*( );
    ▷ conserve stack space ◁
  begin_token_list(*ref_count*, *macro*); *name* ← *warning_index*; *loc* ← *link*(*r*);
  if (*n* > 0) { **if** (*param_ptr* + *n* > *max_param_stack*) { *max_param_stack* ← *param_ptr* + *n*;
    if (*max_param_stack* > *param_size*) *overflow*("parameter␣stack␣size", *param_size*);
    }
    for (*m* ← 0; *m* ≤ *n* − 1; *m*++) *param_stack*[*param_ptr* + *m*] ← *pstack*[*m*];
    param_ptr ← *param_ptr* + *n*;
  }

This code is used in section 389.

391.   At this point, the reader will find it advisable to review the explanation of token list format that was
presented earlier, since many aspects of that format are of importance chiefly in the *macro_call* routine.

The token list might begin with a string of compulsory tokens before the first *match* or *end_match*. In
that case the macro name is supposed to be followed by those tokens; the following program will set $s \equiv null$
to represent this restriction. Otherwise s will be set to the first token of a string that will delimit the next
parameter.

⟨Scan the parameters and make *link*(*r*) point to the macro body; but **return** if an illegal \par is
      detected 391⟩ ≡
  { *scanner_status* ← *matching*; *unbalance* ← 0; *long_state* ← *eq_type*(*cur_cs*);
    if (*long_state* ≥ *outer_call*) *long_state* ← *long_state* − 2;
    do {
      link(*temp_head*) ← *null*;
      if ((*info*(*r*) > *match_token* + 255) ∨ (*info*(*r*) < *match_token*)) *s* ← *null*;
      else { *match_chr* ← *info*(*r*) − *match_token*; *s* ← *link*(*r*); *r* ← *s*; *p* ← *temp_head*; *m* ← 0;
      }
      ⟨Scan a parameter until its delimiter string has been found; or, if $s \leftarrow null$, simply scan the delimiter
          string 392⟩;   ▷now *info*(*r*) is a token whose command code is either *match* or *end_match* ◁
    } **while** (¬(*info*(*r*) ≡ *end_match_token*));
  }

This code is used in section 389.

392.   If *info*(*r*) is a *match* or *end_match* command, it cannot be equal to any token found by *get_token*.
Therefore an undelimited parameter—i.e., a *match* that is immediately followed by *match* or *end_match*—
will always fail the test '*cur_tok* ≡ *info*(*r*)' in the following algorithm.

⟨Scan a parameter until its delimiter string has been found; or, if $s \leftarrow null$, simply scan the delimiter
      string 392⟩ ≡
resume: *get_token*( );   ▷set *cur_tok* to the next token of input ◁
  if (*cur_tok* ≡ *info*(*r*)) ⟨Advance *r*; **goto** *found* if the parameter delimiter has been fully matched,
        otherwise **goto** *resume* 394⟩;
  ⟨Contribute the recently matched tokens to the current parameter, and **goto** *resume* if a partial match
      is still in effect; but abort if $s \leftarrow null$ 397⟩;
  if (*cur_tok* ≡ *par_token*)
    if (*long_state* ≠ *long_call*) ⟨Report a runaway argument and abort 396⟩;
  if (*cur_tok* < *right_brace_limit*)
    if (*cur_tok* < *left_brace_limit*) ⟨Contribute an entire group to the current parameter 399⟩
    else ⟨Report an extra right brace and **goto** *resume* 395⟩
  else ⟨Store the current token, but **goto** *resume* if it is a blank space that would become an undelimited
        parameter 393⟩;
  incr(*m*);
  if (*info*(*r*) > *end_match_token*) **goto** *resume*;
  if (*info*(*r*) < *match_token*) **goto** *resume*;
found:
  if (*s* ≠ *null*) ⟨Tidy up the parameter just scanned, and tuck it away 400⟩

This code is used in section 391.

393. ⟨Store the current token, but **goto** *resume* if it is a blank space that would become an undelimited parameter 393⟩ ≡

  { **if** (*cur_tok* ≡ *space_token*)

      if (*info*(*r*) ≤ *end_match_token*)

        if (*info*(*r*) ≥ *match_token*) **goto** *resume*;

    store_new_token(*cur_tok*);

  }

This code is used in section 392.

394. A slightly subtle point arises here: When the parameter delimiter ends with '**#{**', the token list will have a left brace both before and after the *end_match*. Only one of these should affect the *align_state*, but both will be scanned, so we must make a correction.

⟨Advance *r*; **goto** *found* if the parameter delimiter has been fully matched, otherwise **goto** *resume* 394⟩ ≡

  { *r* ← *link*(*r*);

    if ((*info*(*r*) ≥ *match_token*) ∧ (*info*(*r*) ≤ *end_match_token*)) { **if** (*cur_tok* < *left_brace_limit*)

      decr(*align_state*);

      goto *found*;

    }

    else goto *resume*;

  }

This code is used in section 392.

395. ⟨Report an extra right brace and **goto** *resume* 395⟩ ≡

  { *back_input*( ); *print_err*("Argument␣of␣"); *sprint_cs*(*warning_index*); *print*("␣has␣an␣extra␣}");

    help6("I'␣ve␣run␣across␣a␣'}'␣that␣doesn'␣t␣seem␣to␣match␣anything.",

    "For␣example,␣'\\def\\a#1{...}'␣and␣'\\a}'␣would␣produce",

    "this␣error.␣If␣you␣simply␣proceed␣now,␣the␣'\\par'␣that",

    "I'␣ve␣just␣inserted␣will␣cause␣me␣to␣report␣a␣runaway",

    "argument␣that␣might␣be␣the␣root␣of␣the␣problem.␣But␣if",

    "your␣'}'␣was␣spurious,␣just␣type␣'2'␣and␣it␣will␣go␣away."); *incr*(*align_state*);

    long_state ← *call*; *cur_tok* ← *par_token*; *ins_error*( ); **goto** *resume*;

  }   ▷ a white lie; the \par won't always trigger a runaway ◁

This code is used in section 392.

396. If *long_state* ≡ *outer_call*, a runaway argument has already been reported.

⟨Report a runaway argument and abort 396⟩ ≡

  { **if** (*long_state* ≡ *call*) { *runaway*( ); *print_err*("Paragraph␣ended␣before␣");

    sprint_cs(*warning_index*); *print*("␣was␣complete");

    help3("I␣suspect␣you'␣ve␣forgotten␣a␣'}',␣causing␣me␣to␣apply␣this",

    "control␣sequence␣to␣too␣much␣text.␣How␣can␣we␣recover?",

    "My␣plan␣is␣to␣forget␣the␣whole␣thing␣and␣hope␣for␣the␣best."); *back_error*( );

    }

    pstack[*n*] ← *link*(*temp_head*); *align_state* ← *align_state* − *unbalance*;

    for (*m* ← 0; *m* ≤ *n*; *m*++) *flush_list*(*pstack*[*m*]);

    goto *end*;

  }

This code is used in sections 392 and 399.

397.   When the following code becomes active, we have matched tokens from s to the predecessor of r, and we have found that $cur\_tok \neq info(r)$. An interesting situation now presents itself: If the parameter is to be delimited by a string such as 'ab', and if we have scanned 'aa', we want to contribute one 'a' to the current parameter and resume looking for a 'b'. The program must account for such partial matches and for others that can be quite complex. But most of the time we have $s \equiv r$ and nothing needs to be done.

Incidentally, it is possible for \par tokens to sneak in to certain parameters of non-\long macros. For example, consider a case like '\def\a#1\par!{...}' where the first \par is not followed by an exclamation point. In such situations it does not seem appropriate to prohibit the \par, so TeX keeps quiet about this bending of the rules.

⟨ Contribute the recently matched tokens to the current parameter, and **goto** *resume* if a partial match is still in effect; but abort if $s \leftarrow null$ 397 ⟩ ≡
  if $(s \neq r)$
    if $(s \equiv null)$ ⟨ Report an improper use of the macro and abort 398 ⟩
    else { $t \leftarrow s$;
      do {
        $store\_new\_token(info(t))$; $incr(m)$; $u \leftarrow link(t)$; $v \leftarrow s$;
        loop { **if** $(u \equiv r)$
            if $(cur\_tok \neq info(v))$ **goto** *done*;
            else { $r \leftarrow link(v)$; **goto** *resume*;
            }
          if $(info(u) \neq info(v))$ **goto** *done*;
          $u \leftarrow link(u)$; $v \leftarrow link(v)$;
        }
      done: $t \leftarrow link(t)$;
      } **while** $(\neg(t \equiv r))$;
      $r \leftarrow s$;   ▷ at this point, no tokens are recently matched ◁
    }

This code is used in section 392.

398.   ⟨ Report an improper use of the macro and abort 398 ⟩ ≡
  { $print\_err("Use\_of\_")$; $sprint\_cs(warning\_index)$; $print("\_doesn't\_match\_its\_definition")$;
    $help4("If\_you\_say,\_e.g.,\_`\backslash def\backslash a1\{...\}',\_then\_you\_must\_always"$,
    $"put\_`1'\_after\_`\backslash a',\_since\_control\_sequence\_names\_are"$,
    $"made\_up\_of\_letters\_only.\_The\_macro\_here\_has\_not\_been"$,
    $"followed\_by\_the\_required\_stuff,\_so\_I'm\_ignoring\_it.")$; $error()$; **goto** *end*;
  }

This code is used in section 397.

399.   ⟨ Contribute an entire group to the current parameter 399 ⟩ ≡
  { $unbalance \leftarrow 1$;
    loop { $fast\_store\_new\_token(cur\_tok)$; $get\_token()$;
      if $(cur\_tok \equiv par\_token)$
        if $(long\_state \neq long\_call)$ ⟨ Report a runaway argument and abort 396 ⟩;
      if $(cur\_tok < right\_brace\_limit)$
        if $(cur\_tok < left\_brace\_limit)$ $incr(unbalance)$;
        else { $decr(unbalance)$;
          if $(unbalance \equiv 0)$ **goto** *done1*;
        }
    }
  done1: $rbrace\_ptr \leftarrow p$; $store\_new\_token(cur\_tok)$;
  }

This code is used in section 392.

400.   If the parameter consists of a single group enclosed in braces, we must strip off the enclosing braces. That's why *rbrace_ptr* was introduced.

⟨ Tidy up the parameter just scanned, and tuck it away 400 ⟩ ≡
  { **if** $((m \equiv 1) \wedge (info(p) < right\_brace\_limit))$ { $link(rbrace\_ptr) \leftarrow null$; $free\_avail(p)$;
      $p \leftarrow link(temp\_head)$; $pstack[n] \leftarrow link(p)$; $free\_avail(p)$;
    }
    else $pstack[n] \leftarrow link(temp\_head)$;
    $incr(n)$;
    if $(tracing\_macros > 0)$
      if $((tracing\_stack\_levels \equiv 0) \vee (input\_ptr < tracing\_stack\_levels))$ { $begin\_diagnostic(\,)$;
        $print\_nl(\texttt{""})$; $printn(match\_chr)$; $print\_int(n)$; $print(\texttt{"<-"})$;
        $show\_token\_list(pstack[n-1], null, 1000)$; $end\_diagnostic(false)$;
      }
  }

This code is used in section 392.

401.   ⟨ Show the text of the macro being expanded 401 ⟩ ≡
  { $begin\_diagnostic(\,)$;
    if $(tracing\_stack\_levels > 0)$ {
      if $(input\_ptr < tracing\_stack\_levels)$ { **int** $v \leftarrow input\_ptr$;
        $print\_ln(\,)$; $print\_char(\texttt{'~'})$;
        while $(v-- > 0)$ $print\_char(\texttt{'.'})$;
        $print\_cs(warning\_index)$; $token\_show(ref\_count)$;
      }
      else { $print\_char(\texttt{'~'})$; $print\_char(\texttt{'~'})$; $print\_cs(warning\_index)$;
      }
    }
    else { $print\_ln(\,)$; $print\_cs(warning\_index)$; $token\_show(ref\_count)$;
    }
    $end\_diagnostic(false)$;
  }

This code is used in section 389.

402.   Basic scanning subroutines.   Let's turn now to some procedures that TeX calls upon frequently to digest certain kinds of patterns in the input. Most of these are quite simple; some are quite elaborate. Almost all of the routines call *get_x_token*, which can cause them to be invoked recursively.

403.   The *scan_left_brace* routine is called when a left brace is supposed to be the next non-blank token. (The term "left brace" means, more precisely, a character whose catcode is *left_brace*.) TeX allows \relax to appear before the *left_brace*.

> **static void** *scan_left_brace*(**void**)   ▷ reads a mandatory *left_brace* ◁
> { ⟨ Get the next non-blank non-relax non-call token 404 ⟩;
>   **if** (*cur_cmd* ≠ *left_brace*) { *print_err*("Missing␣{␣inserted");
>   *help4*("A␣left␣brace␣was␣mandatory␣here,␣so␣I've␣put␣one␣in.",
>   "You␣might␣want␣to␣delete␣and/or␣insert␣some␣corrections",
>   "so␣that␣I␣will␣find␣a␣matching␣right␣brace␣soon.",
>   "(If␣you're␣confused␣by␣all␣this,␣try␣typing␣`I}'␣now.)"); *back_error*();

> }

404.   ⟨ Get the next non-blank non-relax non-call token 404 ⟩ ≡
> **do** *get_x_token*(); **while** (¬((*cur_cmd* ≠ *spacer*) ∧ (*cur_cmd* ≠ *relax*)))

This code is used in sections 403, 526, 1078, 1084, 1151, 1160, 1211, 1226, and 1270.

405.   The *scan_optional_equals* routine looks for an optional '=' sign preceded by optional spaces; '\relax' is not ignored here.

> **static void** *scan_optional_equals*(**void**)
> { ⟨ Get the next non-blank non-call token 406 ⟩;
>   **if** (*cur_tok* ≠ *other_token* + '=') *back_input*();
> }

406.   ⟨ Get the next non-blank non-call token 406 ⟩ ≡
> **do** *get_x_token*(); **while** (¬(*cur_cmd* ≠ *spacer*))

This code is used in sections 405, 441, 455, 503, 577, 1045, 1349, 1468, and 1469.

407.   In case you are getting bored, here is a slightly less trivial routine: Given a string of lowercase letters, like 'pt' or 'plus' or 'width', the *scan_keyword* routine checks to see whether the next tokens of input match this string. The match must be exact, except that uppercase letters will match their lowercase counterparts; uppercase equivalents are determined by subtracting 'a' − 'A', rather than using the *uc_code* table, since TEX uses this routine only for its own limited set of keywords.

   If a match is found, the characters are effectively removed from the input and *true* is returned. Otherwise *false* is returned, and the input is left essentially unchanged (except for the fact that some macros may have been expanded, etc.).

```
static bool scan_keyword (char *s)      ▷ look for a given string ◁
{ pointer p;      ▷ tail of the backup list ◁
  pointer q;        ▷ new node being added to the token list via store_new_token ◁

  p ← backup_head; link(p) ← null;
  while (∗s ≠ 0) { get_x_token();      ▷ recursion is possible here ◁
    if ((cur_cs ≡ 0) ∧ ((cur_chr ≡ so(∗s)) ∨ (cur_chr ≡ so(∗s) − 'a' + 'A'))) {
      store_new_token(cur_tok); incr(s);
    }
    else if ((cur_cmd ≠ spacer) ∨ (p ≠ backup_head)) { back_input();
      if (p ≠ backup_head) back_list(link(backup_head));
      return false;
    }
  }
  flush_list(link(backup_head)); return true;
}
```

408.   Here is a procedure that sounds an alarm when mu and non-mu units are being switched.

```
static void mu_error (void)
{ print_err("Incompatible␣glue␣units");
  help1("I'm␣going␣to␣assume␣that␣1mu=1pt␣when␣they're␣mixed."); error();
}
```

409.   The next routine '*scan_something_internal*' is used to fetch internal numeric quantities like '\hsize', and also to handle the '\the' when expanding constructions like '\the\toks0' and '\the\baselineskip'. Soon we will be considering the *scan_int* procedure, which calls *scan_something_internal*; on the other hand, *scan_something_internal* also calls *scan_int*, for constructions like '\catcode`\$' or '\fontdimen 3 \ff'. So we have to declare *scan_int* as a *forward* procedure. A few other procedures are also declared at this point.

```
static void scan_int (void);      ▷ scans an integer value ◁
```

⟨ Declare procedures that scan restricted classes of integers 433 ⟩
⟨ Declare ε-TEX procedures for scanning 1414 ⟩
⟨ Declare procedures that scan font-related stuff 577 ⟩

410. TeX doesn't know exactly what to expect when *scan_something_internal* begins. For example, an integer or dimension or glue value could occur immediately after '\hskip'; and one can even say \the with respect to token lists in constructions like '\xdef\o{\the\output}'. On the other hand, only integers are allowed after a construction like '\count'. To handle the various possibilities, *scan_something_internal* has a *level* parameter, which tells the "highest" kind of quantity that *scan_something_internal* is allowed to produce. Six levels are distinguished, namely *int_val*, *dimen_val*, *glue_val*, *mu_val*, *ident_val*, and *tok_val*.

The output of *scan_something_internal* (and of the other routines *scan_int*, *scan_dimen*, and *scan_glue* below) is put into the global variable *cur_val*, and its level is put into *cur_val_level*. The highest values of *cur_val_level* are special: *mu_val* is used only when *cur_val* points to something in a "muskip" register, or to one of the three parameters \thinmuskip, \medmuskip, \thickmuskip; *ident_val* is used only when *cur_val* points to a font identifier; *tok_val* is used only when *cur_val* points to *null* or to the reference count of a token list. The last two cases are allowed only when *scan_something_internal* is called with *level* ≡ *tok_val*.

If the output is glue, *cur_val* will point to a glue specification, and the reference count of that glue will have been updated to reflect this reference; if the output is a nonempty token list, *cur_val* will point to its reference count, but in this case the count will not have been updated. Otherwise *cur_val* will contain the integer or scaled value in question.

#**define** *int_val* 0   ▷ integer values ◁
#**define** *dimen_val* 1   ▷ dimension values ◁
#**define** *glue_val* 2   ▷ glue specifications ◁
#**define** *mu_val* 3   ▷ math glue specifications ◁
#**define** *ident_val* 4   ▷ font identifier ◁
#**define** *tok_val* 5   ▷ token lists ◁
#**define** *has_factor* $(cur\_hfactor \neq 0 \vee cur\_vfactor \neq 0)$

⟨ Global variables 13 ⟩ +≡
  static int *cur_val*, *cur_hfactor*, *cur_vfactor*;   ▷ value returned by numeric scanners ◁
  static int *cur_val_level*;   ▷ the "level" of this value ◁

411. The hash table is initialized with '\count', '\dimen', '\skip', and '\muskip' all having *internal_register* as their command code; they are distinguished by the *chr_code*, which is either *int_val*, *dimen_val*, *glue_val*, or *mu_val* more than *mem_bot* (dynamic variable-size nodes cannot have these values)

⟨ Put each of TeX's primitives into the hash table 226 ⟩ +≡

428. ⟨Complain that \the can't do this; give zero result 428⟩ ≡
  { *print_err*("You␣can't␣use␣'"); *print_cmd_chr*(*cur_cmd*, *cur_chr*); *print*("'␣after␣");
    print_esc("the"); *help1*("I'm␣forgetting␣what␣you␣said␣and␣using␣zero␣instead."); *error*( );
    if (*level* ≠ *tok_val*) *scanned_result*(0, *dimen_val*)
    else *scanned_result*(0, *int_val*);
  }

This code is used in section 413.

429.   When a *glue_val* changes to a *dimen_val*, we use the width component of the glue; there is no need to decrease the reference count, since it has not yet been increased. When a *dimen_val* changes to an *int_val*, we use scaled points so that the value doesn't actually change. And when a *mu_val* changes to a *glue_val*, the value doesn't change either.

⟨ Convert *cur_val* to a lower level 429 ⟩ ≡
    { **if** (*cur_val_level* ≡ *glue_val*) *cur_val* ← *width*(*cur_val*);
       else if (*cur_val_level* ≡ *mu_val*) *mu_error*( );
       decr(*cur_val_level*);
    }

This code is used in section 413.

430.   If *cur_val* points to a glue specification at this point, the reference count for the glue does not yet include the reference by *cur_val*. If *negative* is *true*, *cur_val_level* is known to be ≤ *mu_val*.

⟨ Fix the reference count, if any, and negate *cur_val* if *negative* 430 ⟩ ≡
    if (*negative*)
       if (*cur_val_level* ≥ *glue_val*) { *cur_val* ← *new_spec*(*cur_val*);
          ⟨ Negate all three glue components of *cur_val* 431 ⟩;
       }
       else { *negate*(*cur_val*); *negate*(*cur_hfactor*); *negate*(*cur_vfactor*); }
    else if ((*cur_val_level* ≥ *glue_val*) ∧ (*cur_val_level* ≤ *mu_val*)) *add_glue_ref*(*cur_val*)

This code is used in section 413.

431.   ⟨ Negate all three glue components of *cur_val* 431 ⟩ ≡
    { *negate*(*width*(*cur_val*)); *negate*(*stretch*(*cur_val*)); *negate*(*shrink*(*cur_val*));
    }

This code is used in sections 430 and 1464.

432.   Our next goal is to write the *scan_int* procedure, which scans anything that TEX treats as an integer. But first we might as well look at some simple applications of *scan_int* that have already been made inside of *scan_something_internal*.

433.   ⟨ Declare procedures that scan restricted classes of integers 433 ⟩ ≡
    static void *scan_eight_bit_int*(**void**)
    { *scan_int*( );
       if ((*cur_val* < 0) ∨ (*cur_val* > 255)) { *print_err*("Bad␣register␣code");
          help2("A␣register␣number␣must␣be␣between␣0␣and␣255.",
          "I␣changed␣this␣one␣to␣zero."); *int_error*(*cur_val*); *cur_val* ← 0;
       }
    }

See also sections 434, 435, 436, 437, and 1495.

This code is used in section 409.

434.   ⟨ Declare procedures that scan restricted classes of integers 433 ⟩ +≡
    static void *scan_char_num*(**void**)
    { *scan_int*( );
       if ((*cur_val* < 0) ∨ (*cur_val* > 255)) { *print_err*("Bad␣character␣code");
          help2("A␣character␣number␣must␣be␣between␣0␣and␣255.",
          "I␣changed␣this␣one␣to␣zero."); *int_error*(*cur_val*); *cur_val* ← 0;
       }
    }

435.   While we're at it, we might as well deal with similar routines that will be needed later.

⟨ Declare procedures that scan restricted classes of integers 433 ⟩ +≡
  static void *scan_four_bit_int*(**void**)
  { *scan_int*( );
    if ((*cur_val* < 0) ∨ (*cur_val* > 15)) { *print_err*("Bad␣number");

  static void *scan_twenty_seven_bit_int*(**void**)
  { *scan_int*( );
    if ((*cur_val* < 0) ∨ (*cur_val* > °777777777)) { *print_err*("Bad␣delimiter␣code");
      help2("A␣numeric␣delimiter␣code␣must␣be␣between␣0␣and␣2^{27}-1.",
      "I␣changed␣this␣one␣to␣zero."); *int_error*(*cur_val*); *cur_val* ← 0;
    }
  }

438.   An integer number can be preceded by any number of spaces and '+' or '−' signs. Then comes either a decimal constant (i.e., radix 10), an octal constant (i.e., radix 8, preceded by ´), a hexadecimal constant (radix 16, preceded by "), an alphabetic constant (preceded by `), or an internal variable. After scanning is complete, *cur_val* will contain the answer, which must be at most $2^{31} - 1 = 2147483647$ in absolute value. The value of *radix* is set to 10, 8, or 16 in the cases of decimal, octal, or hexadecimal constants, otherwise *radix* is set to zero. An optional space follows a constant.

#**define** *octal_token*   (*other_token* + '\'')   ▷ apostrophe, indicates an octal constant ◁
#**define** *hex_token*   (*other_token* + '"')   ▷ double quote, indicates a hex constant ◁
#**define** *alpha_token*   (*other_token* + '`')   ▷ reverse apostrophe, precedes alpha constants ◁
#**define** *point_token*   (*other_token* + '.')   ▷ decimal point ◁
#**define** *continental_point_token*   (*other_token* + ',')   ▷ decimal point, Eurostyle ◁

⟨ Global variables 13 ⟩ +≡
  static small_number *radix*;   ▷ *scan_int* sets this to 8, 10, 16, or zero ◁

439.   We initialize the following global variables just in case *expand* comes into action before any of the basic scanning routines has assigned them a value.

⟨ Set initial values of key variables 21 ⟩ +≡
  cur_val ← 0; *cur_val_level* ← *int_val*; *radix* ← 0; *cur_order* ← *normal*;

440.   The *scan_int* routine is used also to scan the integer part of a fraction; for example, the '3' in '3.14159' will be found by *scan_int*. The *scan_dimen* routine assumes that $cur\_tok \equiv point\_token$ after the integer part of such a fraction has been scanned by *scan_int*, and that the decimal point has been backed up to be scanned again.

> **static void** *scan_int*(**void**)   ▷ sets *cur_val* to an integer ◁
> { **bool** *negative*;   ▷ should the answer be negated? ◁

}

This code is used in section 444.

447. The *scan_dimen* routine is similar to *scan_int*, but it sets *cur_val* to a **scaled** value, i.e., an integral number of sp. One of its main tasks is therefore to interpret the abbreviations for various kinds of units and to convert measurements to scaled points.

There are three parameters: *mu* is *true* if the finite units must be 'mu', while *mu* is *false* if 'mu' units are disallowed; *inf* is *true* if the infinite units 'fil', 'fill', 'filll' are permitted; and *shortcut* is *true* if *cur_val* already contains an integer and only the units need to be considered.

The order of infinity that was found in the case of infinite glue is returned in the global variable *cur_order*.

⟨Global variables 13⟩ +≡
    static glue_ord *cur_order*;   ▷ order of infinity found by *scan_dimen* ◁

448.   Constructions like '−´77 pt' are legal dimensions, so *scan_dimen* may begin with *scan_int*. This explains why it is convenient to use *scan_int* also for the integer part of a decimal fraction.

Several branches of *scan_dimen* work with *cur_val* as an integer and with an auxiliary fraction f, so that the actual quantity of interest is $cur\_val + f/2^{16}$. At the end of the routine, this "unpacked" representation is put into the single word *cur_val*, which suddenly switches significance from **int** to **scaled**.

#**define** *scan_normal_dimen*   *scan_dimen*(*false*, *false*, *false*)

   static void *scan_dimen*(**bool** *mu*, **bool** *inf*, **bool** *shortcut*)   ▷ sets *cur_val* to a dimension ◁

450.   ⟨ Local variables for dimension calculations 450 ⟩ ≡
  int *num*, *denom*;   ▷ conversion ratio for the scanned units ◁
  int *k*, *kk*;   ▷ number of digits in a decimal fraction ◁
  pointer *p*, *q*;   ▷ top of decimal digit stack ◁
  scaled *v*;   ▷ an internal dimension ◁
  int *save_cur_val*;   ▷ temporary storage of *cur_val* ◁
This code is used in section 448.

451.   The following code is executed when *scan_something_internal* was called asking for *mu_val*, when
we really wanted a "mudimen" instead of "muglue."

⟨ Coerce glue to a dimension 451 ⟩ ≡
  if (*cur_val_level* ≥ *glue_val*) { *v* ← *width*(*cur_val*); *delete_glue_ref*(*cur_val*); *cur_val* ← *v*;
  }
This code is used in sections 449 and 455.

452.   When the following code is executed, we have *cur_tok* ≡ *point_token*, but this token has been backed
up using *back_input*; we must first discard it.

It turns out that a decimal point all by itself is equivalent to '0.0'. Let's hope people don't use that fact.

⟨ Scan decimal fraction 452 ⟩ ≡
  { *k* ← 0; *p* ← *null*; *get_token*();   ▷ *point_token* is being re-scanned ◁
    loop { *get_x_token*();
      if ((*cur_tok* > *zero_token* + 9) ∨ (*cur_tok* < *zero_token*)) **goto** *done1*;
      if (*k* < 17)   ▷ digits for *k* ≥ 17 cannot affect the result ◁
      { *q* ← *get_avail*(); *link*(*q*) ← *p*; *info*(*q*) ← *cur_tok* − *zero_token*; *p* ← *q*; *incr*(*k*);
      }
    }
  done1:
    for (*kk* ← *k*; *kk* ≥ 1; *kk*−−) { *dig*[*kk* − 1] ← *info*(*p*); *q* ← *p*; *p* ← *link*(*p*); *free_avail*(*q*);
    }
    f ← *round_decimals*(*k*);
    if (*cur_cmd* ≠ *spacer*) *back_input*();
  }
This code is used in section 448.

453.   Now comes the harder part: At this point in the program, *cur_val* is a nonnegative integer and $f/2^{16}$ is a nonnegative fraction less than 1; we want to multiply the sum of these two quantities by the appropriate factor, based on the specified units, in order to produce a **scaled** result, and we want to do the calculation with fixed point arithmetic that does not overflow.

⟨ Scan units and set *cur_val* to $x \cdot (cur\_val + f/2^{16})$, where there are x sp per unit; **goto** *attach_sign* if the units are internal 453 ⟩ ≡

461.   The final member of TeX's value-scanning trio is *scan_glue*, which makes *cur_val* point to a glue specification. The reference count of that glue spec will take account of the fact that *cur_val* is pointing to it.

   The *level* parameter should be either *glue_val* or *mu_val*.

   Since *scan_dimen* was so much more complex than *scan_int*, we might expect *scan_glue* to be even worse. But fortunately, it is very simple, since most of the work has already been done.

   static void *scan_glue*(**small_number** *level*)   ▷ sets *cur_val* to a glue spec pointer ◁
   { **bool** *negative*;   ▷ should the answer be negated? ◁
     pointer *q*;   ▷ new glue specification ◁
     bool *mu*;   ▷ does *level* ≡ *mu_val*? ◁

     mu ← (*level* ≡ *mu_val*); ⟨Get the next non-blank non-sign token; set *negative* appropriately 441⟩

   if (*scan_keyword*("minus")) { *scan_dimen*(*mu*, *true*, *false*); *shrink*(*q*) ← *cur_val*;
     shrink_order(*q*) ← *cur_order*;
   }
   cur_val ← *q*

This code is used in section 461.

463.   Here's a similar procedure that returns a pointer to a rule node. This routine is called just after TEX
has seen \hrule or \vrule; therefore *cur_cmd* will be either *hrule* or *vrule*. The idea is to store the default
rule dimensions in the node, then to override them if 'height' or 'width' or 'depth' specifications are found
(in any order).

#**define** *default_rule* 26214   ▷ 0.4 pt ◁

  static pointer *scan_rule_spec*(**void**)
  { **pointer** *q*;   ▷ the rule node being created ◁

    q ← *new_rule*( );   ▷ *width*, *depth*, and *height* all equal *null_flag* now ◁
    if (*cur_cmd* ≡ *vrule*) *width*(*q*) ← *default_rule*;
    else { *height*(*q*) ← *default_rule*; *depth*(*q*) ← 0;
    }
  reswitch:
    if (*scan_keyword*("width")) { *scan_normal_dimen*; *width*(*q*) ← *cur_val*; **goto** *reswitch*;
    }
    if (*scan_keyword*("height")) { *scan_normal_dimen*; *height*(*q*) ← *cur_val*; **goto** *reswitch*;
    }
    if (*scan_keyword*("depth")) { *scan_normal_dimen*; *depth*(*q*) ← *cur_val*; **goto** *reswitch*;
    }
    return *q*;
  }

464.   Building token lists.   The token lists for macros and for other things like \mark and \output and \write are produced by a procedure called *scan_toks*.

Before we get into the details of *scan_toks*, let's consider a much simpler task, that of converting the current string into a token list. The *str_toks* function does this; it classifies spaces as type *spacer* and everything else as type *other_char*.

The token list created by *str_toks* begins at *link*(*temp_head*) and ends at the value *p* that is returned. (If *p* ≡ *temp_head*, the list is empty.)

⟨Declare ε-TEX procedures for token lists 1415⟩

    static pointer *str_toks*(**pool_pointer** *b*)   ▷converts *str_pool*[*b* .. *pool_ptr* − 1] to a token list ◁
    { **pointer** *p*;   ▷tail of the token list ◁
      pointer *q*;   ▷new node being added to the token list via *store_new_token* ◁
      halfword *t*;   ▷token being appended ◁
      pool_pointer *k*;   ▷index into *str_pool* ◁
      str_room(1); *p* ← *temp_head*; *link*(*p*) ← *null*; *k* ← *b*;
      while (*k* < *pool_ptr*) { *t* ← *so*(*str_pool*[*k*]);
        if (*t* ≡ '␣') *t* ← *space_token*;
        else *t* ← *other_token* + *t*;
        fast_store_new_token(*t*); *incr*(*k*);
      }
      pool_ptr ← *b*; **return** *p*;
    }

465.   The main reason for wanting *str_toks* is the next function, *the_toks*, which has similar input/output characteristics.

This procedure is supposed to scan something like '\skip\count12', i.e., whatever can follow '\the', and it constructs a token list containing something like '-3.0pt minus 0.5fill'.

    static pointer *the_toks*(**void**)
    { **int** *old_setting*;   ▷holds *selector* setting ◁
      pointer *p*, *q*, *r*;   ▷used for copying a token list ◁
      pool_pointer *b*;   ▷base of temporary string ◁
      small_number *c*;   ▷value of *cur_chr* ◁
      ⟨Handle \unexpanded or \detokenize and **return** 1420⟩;

This code is used in section 470.

473. Now we can't postpone the difficulties any longer; we must bravely tackle *scan_toks*. This function returns a pointer to the tail of a new token list, and it also makes *def_ref* point to the reference count at the head of that list.

There are two boolean parameters, *macro_def* and *xpand*. If *macro_def* is true, the goal is to create the token list for a macro definition; otherwise the goal is to create the token list for some other TeX primitive: `\mark`, `\output`, `\everypar`, `\lowercase`, `\uppercase`, `\message`, `\errmessage`, `\write`, or `\special`. In the latter cases a left brace must be scanned next; this left brace will not be part of the token list, nor will the matching right brace that comes at the end. If *xpand* is false, the token list will simply be copied from the input using *get_token*. Otherwise all expandable tokens will be expanded until unexpandable tokens are left, except that the results of expanding '`\the`' are not expanded further. If both *macro_def* and *xpand* are true, the expansion applies only to the macro body (i.e., to the material following the first *left_brace* character).

The value of *cur_cs* when *scan_toks* begins should be the *eqtb* address of the control sequence to display in "runaway" error messages.

static pointer *scan_toks*(**bool** *macro_def*, **bool** *xpand*)
{ **halfword** *t*;   ▷ token representing the highest parameter number ◁

This code is used in section 477.

480.   Another way to create a token list is via the \read command. The sixteen files potentially usable for reading appear in the following global variables. The value of *read_open*[*n*] will be *closed* if stream number *n* has not been opened or if it has been fully read; *just_open* if an \openin but not a \read has been done; and *normal* if it is open and ready to read the next line.

#**define** *closed*   2   ▷ not open, or at end of file ◁
#**define** *just_open*   1   ▷ newly opened, first line not yet read ◁
⟨Global variables 13⟩ +≡
  static alpha_file *read_file*[16];   ▷ used for \read ◁
  static int8_t *read_open*[17];   ▷ state of *read_file*[*n*] ◁

481.   ⟨Set initial values of key variables 21⟩ +≡
  for (*k* ← 0; *k* ≤ 16; *k*++) *read_open*[*k*] ← *closed*;

482.   The *read_toks* procedure constructs a token list like that for any macro definition, and makes *cur_val*
point to it. Parameter r points to the control sequence that will receive this token list.

> **static void** *read_toks*(**int** n, **pointer** r, **halfword** j)
> { **pointer** p;   ▷ tail of the token list ◁
>   **pointer** q;   ▷ new node being added to the token list via *store_new_token* ◁
>   **int** s;   ▷ saved value of *align_state* ◁
>   **small_number** m;   ▷ stream number ◁
>
>   *scanner_status* ← *defining*; *warning_index* ← r; *def_ref* ← *get_avail*( );

>   *store_new_token*(*end_match_token*);
>   **if** $((n < 0) \lor (n > 15))$ m ← 16; **else** m ← n;
> s ← *align_state*; *align_state* ← 1000000;   ▷ disable tab marks, etc. ◁
>   **do** ⟨Input and store tokens from the next line of the file 483⟩ **while** $(\neg(align\_state \equiv 1000000))$;
>   *cur_val* ← *def_ref*; *scanner_status* ← *normal*; *align_state* ← s;
> }

483.   ⟨Input and store tokens from the next line of the file 483⟩ ≡
>   {
>   *begin_file_reading*( ); *name* ← $m + 1$;
>   **if** (*read_open*[m] ≡ *closed*) ⟨Input for \read from the terminal 484⟩;
>   **else if** (*read_open*[m] ≡ *just_open*) ⟨Input the first line of *read_file*[m] 485⟩
>   **else** ⟨Input the next line of *read_file*[m] 486⟩;
>   *limit* ← *last*;
>   **if** (*end_line_char_inactive*) *decr*(*limit*);
>   **else** *buffer*[*limit*] ← *end_line_char*;
>   *first* ← *limit* + 1; *loc* ← *start*; *state* ← *new_line*;
>   ⟨Handle \readline and **goto** *done* 1445⟩;
>   **loop** { *get_token*( );
>   **if** (*cur_tok* ≡ 0) **goto** *done*;   ▷ *cur_cmd* ≡ *cur_chr* ≡ 0 will occur at the end of the line ◁
>   **if** (*align_state* < 1000000)   ▷ unmatched '}' aborts the line ◁
>   { **do** *get_token*( ); **while** $(\neg(cur\_tok \equiv 0))$;
>   *align_state* ← 1000000; **goto** *done*;
>   }
>   *store_new_token*(*cur_tok*);
>   }
>   *done*: *end_file_reading*( );
>   }

This code is used in section 482.

484.   Here we input on-line into the *buffer* array, prompting the user explicitly if $n \geq 0$. The value of n is
set negative so that additional prompts will not be given in the case of multi-line input.

⟨Input for \read from the terminal 484⟩ ≡
>   **if** (*interaction* > *nonstop_mode*)
>   **if** $(n < 0)$ *prompt_input*("")
>   **else** { *wake_up_terminal*; *print_ln*( ); *sprint_cs*(r); *prompt_input*("="); n ← −1;
>   }
>   **else** *fatal_error*("***␣(cannot␣\\read␣from␣terminal␣in␣nonstop␣modes)")

This code is used in section 483.

485. The first line of a file must be treated specially, since *input_ln* must be told not to start with *get*.

⟨ Input the first line of *read_file*[*m*] 485 ⟩ ≡
 if (*input_ln*(&*read_file*[*m*], *false*)) *read_open*[*m*] ← *normal*;
 else { *a_close*(&*read_file*[*m*]); *read_open*[*m*] ← *closed*;
 }

This code is used in section 483.

486. An empty line is appended at the end of a *read_file*.

⟨ Input the next line of *read_file*[*m*] 486 ⟩ ≡
 { **if** (¬*input_ln*(&*read_file*[*m*], *true*)) { *a_close*(&*read_file*[*m*]); *read_open*[*m*] ← *closed*;
  if (*align_state* ≠ 1000000) { *runaway*( ); *print_err*("File␣ended␣within␣"); *print_esc*("read");
   help1("This␣\\read␣has␣unbalanced␣braces."); *align_state* ← 1000000; *limit* ← 0; *error*( );
  }
 }
 }

This code is used in section 483.

487.   Conditional processing.   We consider now the way TEX handles various kinds of `\if` commands.

#**define** *unless_code* 32   ▷ amount added for '`\unless`' prefix ◁

#**define** *if_char_code* 0   ▷ '`\if`' ◁

    ⟨Cases of *if_test* for *print_cmd_chr* 1448⟩
    default: *print_esc*("if");
    }
  } **break**;

489.   Conditions can be inside conditions, and this nesting has a stack that is independent of the *save_stack*.
  Four global variables represent the top of the condition stack: *cond_ptr* points to pushed-down entries,
if any; *if_limit* specifies the largest code of a *fi_or_else* command that is syntactically legal; *cur_if* is the
name of the current type of conditional; and *if_line* is the line number at which it began.
  If no conditions are currently in progress, the condition stack has the special state *cond_ptr* ≡ *null*,
if_limit ≡ *normal*, *cur_if* ≡ 0, *if_line* ≡ 0. Otherwise *cond_ptr* points to a two-word node; the *type*,
subtype, and *link* fields of the first word contain *if_limit*, *cur_if*, and *cond_ptr* at the next level, and the
second word contains the corresponding *if_line*.

#**define** *if_node_size* 2   ▷ number of words in stack entry for conditionals ◁
#**define** *if_line_field*(A) *mem*[A + 1].*i*
#**define** *if_code* 1   ▷ code for \if... being evaluated ◁
#**define** *fi_code* 2   ▷ code for \fi ◁
#**define** *else_code* 3   ▷ code for \else ◁
#**define** *or_code* 4   ▷ code for \or ◁

⟨Global variables 13⟩ +≡
  static pointer *cond_ptr*;   ▷ top of the condition stack ◁
  static int *if_limit*;   ▷ upper bound on *fi_or_else* codes ◁
  static small_number *cur_if*;   ▷ type of conditional being worked on ◁
  static int *if_line*;   ▷ line where that conditional began ◁

490.   ⟨Set initial values of key variables 21⟩ +≡
  cond_ptr ← *null*; *if_limit* ← *normal*; *cur_if* ← 0; *if_line* ← 0;

491.   ⟨Put each of TeX's primitives into the hash table 226⟩ +≡
  primitive("fi", *fi_or_else*, *fi_code*); *text*(*frozen_fi*) ← *text*(*cur_val*); *eqtb*[*frozen_fi*] ← *eqtb*[*cur_val*];
  primitive("or", *fi_or_else*, *or_code*); *primitive*("else", *fi_or_else*, *else_code*);

492.   ⟨ Cases of *print_cmd_chr* for symbolic printing of primitives 227 ⟩ +≡

case *fi_or_else*:
  if (*chr_code* ≡ *fi_code*) *print_esc*("fi");
  else if (*chr_code* ≡ *or_code*) *print_esc*("or");
  else *print_esc*("else"); **break**;

493.   When we skip conditional text, we keep track of the line number where skipping began, for use in error messages.

⟨ Global variables 13 ⟩ +≡
  static int *skip_line*;   ▷ skipping began here ◁

494.   Here is a procedure that ignores text until coming to an \or, \else, or \fi at the current level of \if ... \fi nesting. After it has acted, *cur_chr* will indicate the token that was found, but *cur_tok* will not be set (because this makes the procedure run faster).

```
static void pass_text(void)
{ int l;      ▷ level of \if ... \fi nesting ◁
  small_number save_scanner_status;      ▷ scanner_status upon entry ◁

  save_scanner_status ← scanner_status; scanner_status ← skipping; l ← 0; skip_line ← line;
  loop { get_next();
    if (cur_cmd ≡ fi_or_else) { if (l ≡ 0) goto done;
      if (cur_chr ≡ fi_code) decr(l);
    }
    else if (cur_cmd ≡ if_test) incr(l);
  }
done: scanner_status ← save_scanner_status;
  if (tracing_ifs > 0) show_cur_cmd_chr();
}
```

495.   When we begin to process a new \if, we set *if_limit* ← *if_code*; then if \or or \else or \fi occurs before the current \if condition has been evaluated, \relax will be inserted. For example, a sequence of commands like '\ifvoid1\else...\fi' would otherwise require something after the '1'.

⟨ Push the condition stack 495 ⟩ ≡
  { *p* ← *get_node*(*if_node_size*); *link*(*p*) ← *cond_ptr*; *type*(*p*) ← *if_limit*; *subtype*(*p*) ← *cur_if*;
    if_line_field(*p*) ← *if_line*; *cond_ptr* ← *p*; *cur_if* ← *cur_chr*; *if_limit* ← *if_code*; *if_line* ← *line*;
  }
This code is used in section 498.

496.   ⟨ Pop the condition stack 496 ⟩ ≡
  { **if** (*if_stack*[*in_open*] ≡ *cond_ptr*) *if_warning*();   ▷ conditionals possibly not properly nested with files ◁
    p ← *cond_ptr*; *if_line* ← *if_line_field*(*p*); *cur_if* ← *subtype*(*p*); *if_limit* ← *type*(*p*);
    cond_ptr ← *link*(*p*); *free_node*(*p*, *if_node_size*);
  }
This code is used in sections 498, 500, 509, and 510.

497.   Here's a procedure that changes the *if_limit* code corresponding to a given value of *cond_ptr*.

> **static void** *change_if_limit*(**small_number** *l*, **pointer** *p*)
> { **pointer** *q*;
>   **if** ($p \equiv cond\_ptr$) *if_limit* $\leftarrow l$;   ▷ that's the easy case ◁
>   **else** { $q \leftarrow cond\_ptr$;
>   **loop** { **if** ($q \equiv null$) *confusion*("if");
>   **if** ($link(q) \equiv p$) { *type*(*q*) $\leftarrow l$; **return**;
>   }
> $q \leftarrow link(q)$;
>   }
>   }
> }

498.   A condition is started when the *expand* procedure encounters an *if_test* command; in that case *expand* reduces to *conditional*, which is a recursive procedure.

> **static void** *conditional*(**void**)
> { **bool** *b*;   ▷ is the condition true? ◁
>   **int** *r*;   ▷ relation to be evaluated ◁
>   **int** *m, n*;   ▷ to be tested against the second operand ◁
>   **pointer** *p, q*;   ▷ for traversing token lists in \ifx tests ◁
>   **small_number** *save_scanner_status*;   ▷ *scanner_status* upon entry ◁
>   **pointer** *save_cond_ptr*;   ▷ *cond_ptr* corresponding to this conditional ◁
>   **small_number** *this_if*;   ▷ type of this conditional ◁
>   **bool** *is_unless*;   ▷ was this if preceded by '\unless' ? ◁
>   **if** (*tracing_ifs* > 0)
>   **if** (*tracing_commands* ≤ 1) *show_cur_cmd_chr*();
>   ⟨Push the condition stack 495⟩; *save_cond_ptr* $\leftarrow cond\_ptr$; *is_unless* $\leftarrow$ (*cur_chr* ≥ *unless_code*);
>   *this_if* $\leftarrow$ *cur_chr* % *unless_code*;
>   ⟨Either process \ifcase or set *b* to the value of a boolean condition 501⟩;
>   **if** (*is_unless*) *b* $\leftarrow \neg b$;
>   **if** (*tracing_commands* > 1) ⟨Display the value of *b* 502⟩;
>   **if** (*b*) { *change_if_limit*(*else_code, save_cond_ptr*); **return**;   ▷ wait for \else or \fi ◁
>   }
>   ⟨Skip to \else or \fi, then **goto** *common_ending* 500⟩;

      help1("I␣was␣expecting␣to␣see␣'<',␣'=',␣or␣'>'.␣Didn't."); *back_error*( ); $r \leftarrow$ '=';
    }
    if (*this_if* ≡ *if_int_code*) *scan_int*( ); **else** *scan_normal_dimen*;
    switch (*r*) {
    case '<': $b \leftarrow (n < cur\_val)$; **break**;
    case '=': $b \leftarrow (n \equiv cur\_val)$; **break**;
    case '>': $b \leftarrow (n > cur\_val)$;
    }
  }
This code is used in section 501.

504.   ⟨Test if an integer is odd 504⟩ ≡
  { *scan_int*( ); $b \leftarrow odd(cur\_val)$;
  }
This code is used in section 501.

505.   ⟨ Test box register status 505 ⟩ ≡
  { *scan_register_num* ( ); *fetch_box* (*p*);
    if (*this_if* ≡ *if_void_code*) *b* ← (*p* ≡ *null*);
    else if (*p* ≡ *null*) *b* ← *false*;
    else if (*this_if* ≡ *if_hbox_code*) *b* ← (*type*(*p*) ≡ *hlist_node*);
    else *b* ← (*type*(*p*) ≡ *vlist_node*);
  }

This code is used in section 501.

506.   An active character will be treated as category 13 following \if\noexpand or following \ifcat\noexpand. We use the fact that active characters have the smallest tokens, among all control sequences.

#**define** *get_x_token_or_active_char*
          { *get_x_token* ( );
            if (*cur_cmd* ≡ *relax*)
              if (*cur_chr* ≡ *no_expand_flag*) { *cur_cmd* ← *active_char*;
                cur_chr ← *cur_tok* − *cs_token_flag* − *active_base*;
              }
          }

⟨ Test if two characters match 506 ⟩ ≡
  { *get_x_token_or_active_char*;
    if ((*cur_cmd* > *active_char*) ∨ (*cur_chr* > 255))   ▷ not a character ◁
    { *m* ← *relax*; *n* ← 256;
    }
    else { *m* ← *cur_cmd*; *n* ← *cur_chr*;
    }
    get_x_token_or_active_char;
    if ((*cur_cmd* > *active_char*) ∨ (*cur_chr* > 255)) { *cur_cmd* ← *relax*; *cur_chr* ← 256;
    }
    if (*this_if* ≡ *if_char_code*) *b* ← (*n* ≡ *cur_chr*); **else** *b* ← (*m* ≡ *cur_cmd*);
  }

This code is used in section 501.

507.   Note that '\ifx' will declare two macros different if one is *long* or *outer* and the other isn't, even though the texts of the macros are the same.
    We need to reset *scanner_status*, since \outer control sequences are allowed, but we might be scanning a macro definition or preamble.

⟨ Test if two tokens match 507 ⟩ ≡
  { *save_scanner_status* ← *scanner_status*; *scanner_status* ← *normal*; *get_next* ( ); *n* ← *cur_cs*;
    p ← *cur_cmd*; *q* ← *cur_chr*; *get_next* ( );
    if (*cur_cmd* ≠ *p*) *b* ← *false*;
    else if (*cur_cmd* < *call*) *b* ← (*cur_chr* ≡ *q*);
    else ⟨ Test if two macro texts match 508 ⟩;
    scanner_status ← *save_scanner_status*;
  }

This code is used in section 501.

508.   Note also that '`\ifx`' decides that macros `\a` and `\b` are different in examples like this:

$$\text{\texttt{\textbackslash def\textbackslash a\{\textbackslash c\}}} \qquad \text{\texttt{\textbackslash def\textbackslash c\{\}}}$$
$$\text{\texttt{\textbackslash def\textbackslash b\{\textbackslash d\}}} \qquad \text{\texttt{\textbackslash def\textbackslash d\{\}}}$$

⟨ Test if two macro texts match 508 ⟩ ≡
  { $p \leftarrow link(cur\_chr)$; $q \leftarrow link(equiv(n))$;   ▷ omit reference counts ◁
    if $(p \equiv q)$ $b \leftarrow true$;
    else { **while** $((p \neq null) \wedge (q \neq null))$
       if $(info(p) \neq info(q))$ $p \leftarrow null$;
       else { $p \leftarrow link(p)$; $q \leftarrow link(q)$;
       }
     $b \leftarrow ((p \equiv null) \wedge (q \equiv null))$;
    }
  }

This code is used in section 507.

509.   ⟨ Select the appropriate case and **return** or **goto** $common\_ending$ 509 ⟩ ≡
  { $scan\_int(\,)$; $n \leftarrow cur\_val$;   ▷ n is the number of cases to pass ◁
    if $(tracing\_commands > 1)$ { $begin\_diagnostic(\,)$; $print("\{case_\sqcup")$; $print\_int(n)$; $print\_char('\}')$;
     $end\_diagnostic(false)$;
    }
    while $(n \neq 0)$ { $pass\_text(\,)$;
     if $(cond\_ptr \equiv save\_cond\_ptr)$
      if $(cur\_chr \equiv or\_code)$ $decr(n)$;
      else goto $common\_ending$;
     else if $(cur\_chr \equiv fi\_code)$ ⟨ Pop the condition stack 496 ⟩;
    }
    $change\_if\_limit(or\_code, save\_cond\_ptr)$; **return**;   ▷ wait for `\or`, `\else`, or `\fi` ◁
  }

This code is used in section 501.

510.   The processing of conditionals is complete except for the following code, which is actually part of *expand*. It comes into play when `\or`, `\else`, or `\fi` is scanned.

⟨ Terminate the current conditional and skip to `\fi` 510 ⟩ ≡
  { **if** $(tracing\_ifs > 0)$
    if $(tracing\_commands \leq 1)$ $show\_cur\_cmd\_chr(\,)$;
    if $(cur\_chr > if\_limit)$
    if $(if\_limit \equiv if\_code)$ $insert\_relax(\,)$;   ▷ condition not yet evaluated ◁
    else { $print\_err("Extra_\sqcup")$; $print\_cmd\_chr(fi\_or\_else, cur\_chr)$;
     $help1("I'm_\sqcup ignoring_\sqcup this;_\sqcup it_\sqcup doesn't_\sqcup match_\sqcup any_\sqcup \backslash\backslash if.")$; $error(\,)$;
    }
    else { **while** $(cur\_chr \neq fi\_code)$ $pass\_text(\,)$;   ▷ skip to `\fi` ◁
    ⟨ Pop the condition stack 496 ⟩;
    }
  }

This code is used in section 367.

511.   File names.   It's time now to fret about file names. Besides the fact that different operating systems treat files in different ways, we must cope with the fact that completely different naming conventions are used by different groups of people. The following programs show what is required for one particular operating system; similar routines for other systems are not difficult to devise.

TeX assumes that a file name has three parts: the name proper; its "extension"; and a "file area" where it is found in an external file system. The extension of an input file or a write file is assumed to be '`.tex`' unless otherwise specified; it is '`.log`' on the transcript file that records each run of TeX; it is '`.tfm`' on the font metric files that describe characters in the fonts TeX uses; it is '`.dvi`' on the output files that specify typesetting information; and it is '`.fmt`' on the format files written by `INITEX` to initialize TeX. The file area can be arbitrary on input files, but files are usually output to the user's current area. If an input file cannot be found on the specified area, TeX will look for it on a special system area; this special area is intended for commonly used input files like `webmac.tex`.

Simple uses of TeX refer only to file names that have no explicit extension or area. For example, a person usually says '`\input paper`' or '`\font\tenrm = helvetica`' instead of '`\input paper.new`' or '`\font\tenrm = <csd.knuth>test`'. Simple file names are best, because they make the TeX source files portable; whenever a file name consists entirely of letters and digits, it should be treated in the same way by all implementations of TeX. However, users need the ability to refer to other files in their environment, especially when responding to error messages concerning unopenable files; therefore we want to let them use the syntax that appears in their favorite operating system.

The following procedures don't allow spaces to be part of file names; but some users seem to like names that are spaced-out. System-dependent changes to allow such things should probably be made with reluctance, and only when an entire file name that includes spaces is "quoted" somehow.

512.   In order to isolate the system-dependent aspects of file names, the system-independent parts of TeX are expressed in terms of three system-dependent procedures called *begin_name*, *more_name*, and *end_name*. In essence, if the user-specified characters of the file name are $c_1 \ldots c_n$, the system-independent driver program does the operations

$$begin\_name;\; more\_name(c_1);\; \ldots\; ;\; more\_name(c_n);\; end\_name.$$

These three procedures communicate with each other via global variables. Afterwards the file name will appear in the string pool as three strings called *cur_name*, *cur_area*, and *cur_ext*; the latter two are null (i.e., `""`), unless they were explicitly specified by the user.

Actually the situation is slightly more complicated, because TeX needs to know when the file name ends. The *more_name* routine is a function (with side effects) that returns *true* on the calls $more\_name(c_1)$, $\ldots$, $more\_name(c_{n-1})$. The final call $more\_name(c_n)$ returns *false*; or, it returns *true* and the token following c_n is something like '`\hbox`' (i.e., not a character). In other words, *more_name* is supposed to return *true* unless it is sure that the file name has been completely scanned; and *end_name* is supposed to be able to finish the assembly of *cur_name*, *cur_area*, and *cur_ext* regardless of whether $more\_name(c_n)$ returned *true* or *false*.

⟨ Global variables 13 ⟩ +≡
  static str_number *cur_name*;   ▷ name of file just scanned ◁
  static str_number *cur_area*;   ▷ file area just scanned, or `""` ◁
  static str_number *cur_ext*;   ▷ file extension just scanned, or `""` ◁

513. The file names we shall deal with for illustrative purposes have the following structure: If the name contains '>' or ':', the file area consists of all characters up to and including the final such character; otherwise the file area is null. If the remaining file name contains '.', the file extension consists of all such characters from the first remaining '.' to the end, otherwise the file extension is null.

We can scan such file names easily by using two global variables that keep track of the occurrences of area and extension delimiters:

⟨ Global variables 13 ⟩ +≡
  static pool_pointer *area_delimiter*;   ▷ the most recent '>' or ':', if any ◁
  static pool_pointer *ext_delimiter*;   ▷ the relevant '.', if any ◁

514. Input files that can't be found in the user's area may appear in a standard system area called *TEX_area*. Font metric files whose areas are not given explicitly are assumed to appear in a standard system area called *TEX_font_area*. These system area names will, of course, vary from place to place.

#**define** *TEX_area* "TeXinputs/"
#**define** *TEX_font_area* "TeXfonts/"

515. Here now is the first of the system-dependent routines for file name scanning.

  static bool *quoted_filename*;

  static void *begin_name*(**void**)
  { *area_delimiter* ← 0; *ext_delimiter* ← 0; *quoted_filename* ← *false*;
  }

516. And here's the second. The string pool might change as the file name is being scanned, since a new \csname might be entered; therefore we keep *area_delimiter* and *ext_delimiter* relative to the beginning of the current string, instead of assigning an absolute address like *pool_ptr* to them.

  static bool *more_name*(**ASCII_code** *c*)
  { **if** (*c* ≡ '␣' ∧ ¬*quoted_filename*) **return** *false*;
    else if (*c* ≡ '"') { *quoted_filename* ← ¬*quoted_filename*; **return** *true*;
    }
    else { *str_room*(1); *append_char*(*c*);   ▷ contribute *c* to the current string ◁
      if (IS_DIR_SEP(*c*)) { *area_delimiter* ← *cur_length*; *ext_delimiter* ← 0;
      }
      else if (*c* ≡ '.') *ext_delimiter* ← *cur_length*;
      return *true*;
    }
  }

517. The third.

  static void *end_name*(**void**)
  { **if** (*str_ptr* + 3 > *max_strings*) *overflow*("number␣of␣strings", *max_strings* − *init_str_ptr*);
    if (*area_delimiter* ≡ 0) *cur_area* ← *empty_string*;
    else { *cur_area* ← *str_ptr*; *str_start*[*str_ptr* + 1] ← *str_start*[*str_ptr*] + *area_delimiter*; *incr*(*str_ptr*);
    }
    if (*ext_delimiter* ≡ 0) { *cur_ext* ← *empty_string*; *cur_name* ← *make_string*( );
    }
    else { *cur_name* ← *str_ptr*;
      str_start[*str_ptr* + 1] ← *str_start*[*str_ptr*] + *ext_delimiter* − *area_delimiter* − 1; *incr*(*str_ptr*);
      cur_ext ← *make_string*( );
    }
  }

518.   Conversely, here is a routine that takes three strings and prints a file name that might have produced
them. (The routine is system dependent, because some operating systems put the file area last instead of
first.)

⟨ Basic printing procedures 56 ⟩ +≡
  static void *print_file_name*(**int** *n*, **int** *a*, **int** *e*)
  { *slow_print*(*a*); *slow_print*(*n*); *slow_print*(*e*);
  }

519.   Another system-dependent routine is needed to convert three internal TEX strings into the
name_of_file value that is used to open files. The present code allows both lowercase and uppercase letters
in the file name.

#**define** *append_to_name*(*A*)
         { *c* ← *A*; *incr*(*k*);
            if (*k* ≤ *file_name_size*) *name_of_file*[*k*] ← *xchr*[*c*];
         }
  static void *pack_file_name*(**str_number** *n*, **str_number** *a*, **str_number** *e*, **char** *∗f*)
  { **int** *k*;   ▷ number of positions filled in *name_of_file* ◁
    ASCII_code *c*;   ▷ character being packed ◁
    int *j*;   ▷ index into *str_pool* ◁
    k ← 0;
    for (*j* ← *str_start*[*a*]; *j* ≤ *str_start*[*a* + 1] − 1; *j*++) *append_to_name*(*so*(*str_pool*[*j*]))
    for (*j* ← *str_start*[*n*]; *j* ≤ *str_start*[*n* + 1] − 1; *j*++) *append_to_name*(*so*(*str_pool*[*j*]))
    if (*f* ≡ Λ)
       for (*j* ← *str_start*[*e*]; *j* ≤ *str_start*[*e* + 1] − 1; *j*++) *append_to_name*(*so*(*str_pool*[*j*]))
    else
       while (*∗f* ≠ 0) *append_to_name*(*so*(*∗f*++))
    if (*k* ≤ *file_name_size*) *name_length* ← *k*; **else** *name_length* ← *file_name_size*;
    name_of_file[*name_length* + 1] ← 0;
  }

520.   TEX Live does not use the global variable *TEX_format_default*. It is no longer needed to supply the
text for default system areas and extensions related to format files.

521.   Consequently TEX Live does not need the initialization of *TEX_format_default* either.

522.   And TEX Live does not check the length of *TEX_format_default*.

523.   The *format_extension*, however, is needed by TEX Live to create the format name from the job name.
#**define** *format_extension* ".fmt"

524.   This part of the program becomes active when a "virgin" TEX is trying to get going, just after the
preliminary initialization, or when the user is substituting another format file by typing '&' after the initial
'**' prompt. The buffer contains the first line of input in *buffer*[*loc* .. (*last* − 1)], where *loc* < *last* and
buffer[*loc*] ≠ '␣'.
   TEX Live uses the kpathsearch library to implement access to files. *open_fmt_file* is declared here and
the actual implementation is in the section on TEX Live Integration.
⟨ Declare the function called *open_fmt_file* 524 ⟩ ≡
  static bool *open_fmt_file*(**void**);
This code is used in section 1303.

525.   Operating systems often make it possible to determine the exact name (and possible version number) of a file that has been opened. The following routine, which simply makes a T$_E$X string from the value of *name_of_file*, should ideally be changed to deduce the full name of file f, which is the file most recently opened, if it is possible to do this in a Pascal program.

This routine might be called after string memory has overflowed, hence we dare not use '*str_room*'.

static str_number *make_name_string*(**void**)
{ **int** k;   ▷ index into *name_of_file* ◁

  if ((*pool_ptr* + *name_length* > *pool_size*) ∨ (*str_ptr* ≡ *max_strings*) ∨ (*cur_length* > 0)) **return** '?';
  else { **for** (k ← 1; k ≤ *name_length*; k++) *append_char*(*xord*[*name_of_file*[k]]);
    return *make_string*( );
  }
}
static str_number *a_make_name_string*(**alpha_file** *∗f*)
{ **return** *make_name_string*( );
}
static str_number *b_make_name_string*(**byte_file** *∗f*)
{ **return** *make_name_string*( );
}
#ifdef INIT
static str_number *w_make_name_string*(**word_file** *∗f*)
{ **return** *make_name_string*( );
}
#endif

526.   Now let's consider the "driver" routines by which T$_E$X deals with file names in a system-independent manner. First comes a procedure that looks for a file name. There are two ways to specify the file name: as a general text argument or as a token (after expansion). The traditional token delimiter is the space. For a file name, however, a double quote is used as the token delimiter if the token starts with a double quote.

Once the *area_delimiter* and the *ext_delimiter* are defined, the final processing is shared for all variants.

When starting, \relax is skipped as well as blanks and non-calls. Then a test for the *left_brace* will branch to the code for scanning a general text.

static void *scan_file_name*(**void**)
{ **pool_pointer** j, k;   ▷ index into *str_pool* ◁
  int *old_setting*;   ▷ holds *selector* setting ◁

  name_in_progress ← *true*; *begin_name*( ); ⟨Get the next non-blank non-relax non-call token *404*⟩;
  if (*cur_cmd* ≡ *left_brace*) ⟨Define a general text file name and **goto** *done* *1864*⟩
  loop { **if** ((*cur_cmd* > *other_char*) ∨ (*cur_chr* > 255))   ▷ not a character ◁
    { *back_input*( ); **goto** *done*;
    }
#if 0   ▷ This is from pdftex-final.ch. I don't know these 'some cases', and I am not sure whether the name
      should end even if quoting is on. ◁
      ▷ If *cur_chr* is a space and we're not scanning a token list, check whether we're at the end of the
      buffer. Otherwise we end up adding spurious spaces to file names in some cases. ◁
    if (*cur_chr* ≡ '␣' ∧ *state* ≠ *token_list* ∧ *loc* > *limit*) **goto** *done*;
#endif
    if (¬*more_name*(*cur_chr*)) **goto** *done*;
    get_x_token( );
  }
  done: *end_name*( ); *name_in_progress* ← *false*;
}

527. The global variable *name_in_progress* is used to prevent recursive use of *scan_file_name*, since the *begin_name* and other procedures communicate via global variables. Recursion would arise only by devious tricks like '\input\input f'; such attempts at sabotage must be thwarted. Furthermore, *name_in_progress* prevents \input from being initiated when a font size specification is being scanned.

Another global variable, *job_name*, contains the file name that was first \input by the user. This name is extended by '.log' and '.dvi' and '.fmt' in the names of TeX's output files.

⟨ Global variables 13 ⟩ +≡
   static bool *name_in_progress*;   ▷ is a file name being scanned? ◁
   static str_number *job_name*;   ▷ principal file name ◁
   static bool *log_opened*;   ▷ has the transcript file been opened? ◁

528. Initially *job_name* ≡ 0; it becomes nonzero as soon as the true name is known. We have *job_name* ≡ 0 if and only if the 'log' file has not been opened, except of course for a short time just after *job_name* has become nonzero.

⟨ Initialize the output routines 55 ⟩ +≡
   job_name ← 0; *name_in_progress* ← *false*; *log_opened* ← *false*;

529. Here is a routine that manufactures the output file names, assuming that *job_name* ≠ 0. It ignores and changes the current settings of *cur_area* and *cur_ext*.

#**define** *pack_cur_name*(*A*)
      if (*cur_ext* ≡ *empty_string*) *pack_file_name*(*cur_name*, *cur_area*, *cur_ext*, *A*);
      else *pack_file_name*(*cur_name*, *cur_area*, *cur_ext*, Λ)

   static void *pack_job_name*(**char** ∗*s*)   ▷ *s* ≡ ".log", ".dvi", or *format_extension* ◁
   { *cur_area* ← *empty_string*; *cur_ext* ← *empty_string*; *cur_name* ← *job_name*; *pack_cur_name*(*s*);
   }

530. If some trouble arises when TeX tries to open a file, the following routine calls upon the user to supply another file name. Parameter *s* is used in the error message to identify the type of file; parameter *e* is the default extension if none is given. We handle the specification of a file name with possibly spaces in double quotes (the last one is optional if this is the end of line i.e. the end of the buffer). Upon exit from the routine, variables *cur_name*, *cur_area*, *cur_ext*, and *name_of_file* are ready for another attempt at file opening.

   static void *prompt_file_name*(**char** ∗*s*, **char** ∗*e*)
   { **int** *k*;   ▷ index into *buffer* ◁

     if (*interaction* ≡ *scroll_mode*) *wake_up_terminal*;
     if (*strcmp*(*s*, "input␣file␣name") ≡ 0) *print_err*("I␣can't␣find␣file␣'");
     else *print_err*("I␣can't␣write␣on␣file␣'");
     print_file_name(*cur_name*, *cur_area*, *cur_ext*); *print*("'.");
     if (*strcmp*(*e*, ".tex") ≡ 0) *show_context*( );
     print_nl("Please␣type␣another␣"); *print*(*s*);
     if (*interaction* < *scroll_mode*) *fatal_error*("***␣(job␣aborted,␣file␣error␣in␣nonstop␣mode)");
     clear_terminal; *prompt_input*(":␣"); ⟨ Scan file name in the buffer 531 ⟩;
     pack_cur_name(*e*);
   }

531.   ⟨Scan file name in the buffer 531⟩ ≡
  { *begin_name* ( ); $k \leftarrow$ *first*;
    while ((*buffer* [k] ≡ '␣') ∧ ($k <$ *last*)) *incr* (k);
    loop { **if** ($k ≡$ *last*) **goto** *done*;
      if (¬*more_name* (*buffer* [k])) **goto** *done*;
      incr (k);
    }
  done: *end_name* ( );
  }

This code is used in section 530.

532.   Here's an example of how these conventions are used. Whenever it is time to ship out a box of stuff, we shall use the macro *ensure_dvi_open*.

#**define** *ensure_dvi_open*
      if (*output_file_name* ≡ 0) { **if** (*job_name* ≡ 0) *open_log_file* ( );
      pack_job_name (".dvi");
      while (¬*b_open_out* (&*dvi_file*)) *prompt_file_name* ("file␣name␣for␣output", ".dvi");
      output_file_name ← *b_make_name_string* (&*dvi_file*);
      }

⟨Global variables 13⟩ +≡
  static byte_file *dvi_file*;   ▷ the device-independent output goes here ◁
  static str_number *output_file_name*;   ▷ full name of the output file ◁
  static str_number *log_name*;   ▷ full name of the log file ◁

533.   ⟨Initialize the output routines 55⟩ +≡
  output_file_name ← 0;

534.   The *open_log_file* routine is used to open the transcript file and to help it catch up to what has previously been printed on the terminal.

  static void *open_log_file* (**void**)
  { **int** *old_setting*;   ▷ previous *selector* setting ◁
    int *k*;   ▷ index into *months* and *buffer* ◁
    int *l*;   ▷ end of first input line ◁
    char *months* [ ] ← "␣JANFEBMARAPRMAYJUNJULAUGSEPOCTNOVDEC";   ▷ abbreviations of month names ◁
    old_setting ← *selector*;
    if (*job_name* ≡ 0) *job_name* ← *s_no* (*c_job_name* ? *c_job_name* : "texput");   ▷ TEX Live ◁
    pack_job_name (".fls"); *recorder_change_filename* ((**char** ∗) *name_of_file* + 1);
    pack_job_name (".log");
    while (¬*a_open_out* (&*log_file*)) ⟨Try to get a different log file name 535⟩;
    log_name ← *a_make_name_string* (&*log_file*); *selector* ← *log_only*; *log_opened* ← *true*;
    ⟨Print the banner line, including the date and time 536⟩;
    input_stack [*input_ptr*] ← *cur_input*;   ▷ make sure bottom level is in memory ◁
    print_nl ("∗∗"); *l* ← *input_stack* [0].*limit_field*;   ▷ last position of first line ◁
    if (*buffer* [*l*] ≡ *end_line_char*) *decr* (*l*);
    for (*k* ← 1; *k* ≤ *l*; *k*++) *printn* (*buffer* [*k*]);
    print_ln ( );   ▷ now the transcript file contains the first line of input ◁
    selector ← *old_setting* + 2;   ▷ *log_only* or *term_and_log* ◁
  }

535.   Sometimes *open_log_file* is called at awkward moments when TeX is unable to print error messages or even to *show_context*. The *prompt_file_name* routine can result in a *fatal_error*, but the *error* routine will not be invoked because *log_opened* will be false.

The normal idea of *batch_mode* is that nothing at all should be written on the terminal. However, in the unusual case that no log file could be opened, we make an exception and allow an explanatory message to be seen.

Incidentally, the program always refers to the log file as a '`transcript file`', because some systems cannot use the extension '`.log`' for this file.

⟨ Try to get a different log file name 535 ⟩ ≡
  { *selector* ← *term_only*; *prompt_file_name*("transcript␣file␣name", ".log");
  }

This code is used in section 534.

536.   ⟨ Print the banner line, including the date and time 536 ⟩ ≡
  { *wlog*("%s", *banner*); *slow_print*(*format_ident*); *print*("␣␣"); *print_int*(*sys_day*); *print_char*('␣');
    for (*k* ← 3 * *sys_month* − 2; *k* ≤ 3 * *sys_month*; *k*++) *wlog*("%c", *months*[*k*]);
    print_char('␣'); *print_int*(*sys_year*); *print_char*('␣'); *print_two*(*sys_time*/60); *print_char*(':');
    print_two(*sys_time* % 60);
    if (*eTeX_ex*) { ; *wlog_cr*; *wlog*("entering␣extended␣mode");
    }
    if (*Prote_ex*) { ; *wlog_cr*; *wlog*("entering␣Prote␣mode");
    }
  }

This code is used in section 534.

537.   Let's turn now to the procedure that is used to initiate file reading when an '\input' command is being processed. Beware: For historic reasons, this code foolishly conserves a tiny bit of string pool space; but that can confuse the interactive 'E' option.

> **static void** *start_input*(**void**)   ▷ TeX will \input something ◁
> { *scan_file_name*( );   ▷ set *cur_name* to desired file name ◁
>   *pack_cur_name*("");
>   **loop** { *begin_file_reading*( );   ▷ set up *cur_file* and new level of input ◁
>   **if** (*kpse_in_name_ok*((**char** ∗) *name_of_file* + 1) ∧ *a_open_in*(&*cur_file*)) **goto** *done*;
>   *end_file_reading*( );   ▷ remove the level that didn't work ◁
>   *prompt_file_name*("input␣file␣name", ".tex");
>   }
> *done*: *name* ← *a_make_name_string*(&*cur_file*);
>   **if** (*source_filename_stack*[*in_open*] ≠ Λ) *free*(*source_filename_stack*[*in_open*]);
>   *source_filename_stack*[*in_open*] ← *strdup*((**char** ∗) *name_of_file* + 1);   ▷ TeX Live ◁
>   **if** (*full_source_filename_stack*[*in_open*] ≠ Λ) *free*(*full_source_filename_stack*[*in_open*]);
>   *full_source_filename_stack*[*in_open*] ← *strdup*(*full_name_of_file*);
>   **if** (*job_name* ≡ 0) { **if** (*c_job_name* ≡ Λ) *job_name* ← *cur_name*;
>   **else** *job_name* ← *s_no*(*c_job_name*);
>   *open_log_file*( );   ▷ TeX Live ◁
>   }   ▷ *open_log_file* doesn't *show_context*, so *limit* and *loc* needn't be set to meaningful values yet ◁
>   **if** (*term_offset* + *strlen*(*full_source_filename_stack*[*in_open*]) > *max_print_line* − 2) *print_ln*( );
>   **else if** ((*term_offset* > 0) ∨ (*file_offset* > 0)) *print_char*('␣');
>   *print_char*('('); *incr*(*open_parens*); *print*(*full_source_filename_stack*[*in_open*]); *update_terminal*;

>   { *flush_string*; *name* ← *cur_name*;
>   }
>   ⟨ Read the first line of the new file 538 ⟩;
>   }

538.   Here we have to remember to tell the *input_ln* routine not to start with a *get*. If the file is empty, it is considered to contain a single blank line.

⟨ Read the first line of the new file 538 ⟩ ≡
>   { *line* ← 1;
>   **if** (*input_ln*(&*cur_file*, *false*)) *do_nothing*;
>   *firm_up_the_line*( );

>   **else** *buffer*[*limit*] ← *end_line_char*;
>   *first* ← *limit* + 1; *loc* ← *start*;
>   }

This code is used in section 537.

539.   Font metric data.   TeX gets its knowledge about fonts from font metric files, also called `TFM` files; the 'T' in 'TFM' stands for TeX, but other programs know about them too.

The information in a `TFM` file appears in a sequence of 8-bit bytes. Since the number of bytes is always a multiple of 4, we could also regard the file as a sequence of 32-bit words, but TeX uses the byte interpretation. The format of `TFM` files was designed by Lyle Ramshaw in 1980. The intent is to convey a lot of different kinds of information in a compact but useful form.

⟨ Global variables 13 ⟩ +≡
  static byte_file *tfm_file* ;

540.   The first 24 bytes (6 words) of a `TFM` file contain twelve 16-bit integers that give the lengths of the various subsequent portions of the file. These twelve integers are, in order:

$$
\begin{aligned}
lf &= \text{length of the entire file, in words;} \\
lh &= \text{length of the header data, in words;} \\
bc &= \text{smallest character code in the font;} \\
ec &= \text{largest character code in the font;} \\
nw &= \text{number of words in the width table;} \\
nh &= \text{number of words in the height table;} \\
nd &= \text{number of words in the depth table;} \\
ni &= \text{number of words in the italic correction table;} \\
nl &= \text{number of words in the lig/kern table;} \\
nk &= \text{number of words in the kern table;} \\
ne &= \text{number of words in the extensible character table;} \\
np &= \text{number of font parameter words.}
\end{aligned}
$$

They are all nonnegative and less than 2^{15}. We must have $bc - 1 \leq ec \leq 255$, and

$$lf \equiv 6 + lh + (ec - bc + 1) + nw + nh + nd + ni + nl + nk + ne + np.$$

Note that a font may contain as many as 256 characters (if $bc \equiv 0$ and $ec \equiv 255$), and as few as 0 characters (if $bc \equiv ec + 1$).

Incidentally, when two or more 8-bit bytes are combined to form an integer of 16 or more bits, the most significant bytes appear first in the file. This is called BigEndian order.

541.   The rest of the `TFM` file may be regarded as a sequence of ten data arrays having the informal specification

$$
\begin{aligned}
header &: \textbf{array} \ [0 \mathbin{..} lh - 1] \ \textbf{of} \ stuff \\
char\_info &: \textbf{array} \ [bc \mathbin{..} ec] \ \textbf{of} \ char\_info\_word \\
width &: \textbf{array} \ [0 \mathbin{..} nw - 1] \ \textbf{of} \ fix\_word \\
height &: \textbf{array} \ [0 \mathbin{..} nh - 1] \ \textbf{of} \ fix\_word \\
depth &: \textbf{array} \ [0 \mathbin{..} nd - 1] \ \textbf{of} \ fix\_word \\
italic &: \textbf{array} \ [0 \mathbin{..} ni - 1] \ \textbf{of} \ fix\_word \\
lig\_kern &: \textbf{array} \ [0 \mathbin{..} nl - 1] \ \textbf{of} \ lig\_kern\_command \\
kern &: \textbf{array} \ [0 \mathbin{..} nk - 1] \ \textbf{of} \ fix\_word \\
exten &: \textbf{array} \ [0 \mathbin{..} ne - 1] \ \textbf{of} \ extensible\_recipe \\
param &: \textbf{array} \ [1 \mathbin{..} np] \ \textbf{of} \ fix\_word
\end{aligned}
$$

The most important data type used here is a *fix_word*, which is a 32-bit representation of a binary fraction. A *fix_word* is a signed quantity, with the two's complement of the entire word used to represent negation. Of the 32 bits in a *fix_word*, exactly 12 are to the left of the binary point; thus, the largest *fix_word* value is $2048 - 2^{-20}$, and the smallest is -2048. We will see below, however, that all but two of the *fix_word* values must lie between -16 and $+16$.

542.   The first data array is a block of header information, which contains general facts about the font. The header must contain at least two words, *header*[0] and *header*[1], whose meaning is explained below. Additional header information of use to other software routines might also be included, but TeX82 does not need to know about such details. For example, 16 more words of header information are in use at the Xerox Palo Alto Research Center; the first ten specify the character coding scheme used (e.g., 'XEROX text' or 'TeX math symbols'), the next five give the font identifier (e.g., 'HELVETICA' or 'CMSY'), and the last gives the "face byte." The program that converts DVI files to Xerox printing format gets this information by looking at the TFM file, which it needs to read anyway because of other information that is not explicitly repeated in DVI format.

header[0] is a 32-bit check sum that TeX will copy into the DVI output file. Later on when the DVI file is printed, possibly on another computer, the actual font that gets used is supposed to have a check sum that agrees with the one in the TFM file used by TeX. In this way, users will be warned about potential incompatibilities. (However, if the check sum is zero in either the font file or the TFM file, no check is made.) The actual relation between this check sum and the rest of the TFM file is not important; the check sum is simply an identification number with the property that incompatible fonts almost always have distinct check sums.

header[1] is a *fix_word* containing the design size of the font, in units of TeX points. This number must be at least 1.0; it is fairly arbitrary, but usually the design size is 10.0 for a "10 point" font, i.e., a font that was designed to look best at a 10-point size, whatever that really means. When a TeX user asks for a font 'at δ pt', the effect is to override the design size and replace it by δ, and to multiply the x and y coordinates of the points in the font image by a factor of δ divided by the design size. *All other dimensions in the* TFM *file are fix_word numbers in design-size units*, with the exception of *param*[1] (which denotes the slant ratio). Thus, for example, the value of *param*[6], which defines the em unit, is often the *fix_word* value $2^{20} = 1.0$, since many fonts have a design size equal to one em. The other dimensions must be less than 16 design-size units in absolute value; thus, *header*[1] and *param*[1] are the only *fix_word* entries in the whole TFM file whose first byte might be something besides 0 or 255.

543.   Next comes the *char_info* array, which contains one *char_info_word* per character. Each word in this part of the file contains six fields packed into four bytes as follows.

first byte: *width_index* (8 bits)
second byte: *height_index* (4 bits) times 16, plus *depth_index* (4 bits)
third byte: *italic_index* (6 bits) times 4, plus *tag* (2 bits)
fourth byte: *rem* (8 bits)

The actual width of a character is *width*[*width_index*], in design-size units; this is a device for compressing information, since many characters have the same width. Since it is quite common for many characters to have the same height, depth, or italic correction, the TFM format imposes a limit of 16 different heights, 16 different depths, and 64 different italic corrections.

The italic correction of a character has two different uses. (a) In ordinary text, the italic correction is added to the width only if the TeX user specifies '\/' after the character. (b) In math formulas, the italic correction is always added to the width, except with respect to the positioning of subscripts.

Incidentally, the relation *width*[0] = *height*[0] = *depth*[0] = *italic*[0] = 0 should always hold, so that an index of zero implies a value of zero. The *width_index* should never be zero unless the character does not exist in the font, since a character is valid if and only if it lies between *bc* and *ec* and has a nonzero *width_index*.

544.   The *tag* field in a *char_info_word* has four values that explain how to interpret the *rem* field.

tag ≡ 0 (*no_tag*) means that *rem* is unused.

tag ≡ 1 (*lig_tag*) means that this character has a ligature/kerning program starting at position *rem* in the *lig_kern* array.

tag ≡ 2 (*list_tag*) means that this character is part of a chain of characters of ascending sizes, and not the largest in the chain. The *rem* field gives the character code of the next larger character.

tag ≡ 3 (*ext_tag*) means that this character code represents an extensible character, i.e., a character that is built up of smaller pieces so that it can be made arbitrarily large. The pieces are specified in *exten*[*rem*].

Characters with *tag* ≡ 2 and *tag* ≡ 3 are treated as characters with *tag* ≡ 0 unless they are used in special circumstances in math formulas. For example, the \sum operation looks for a *list_tag*, and the \left operation looks for both *list_tag* and *ext_tag*.

#**define** *no_tag*   0   ▷ vanilla character ◁
#**define** *lig_tag*   1   ▷ character has a ligature/kerning program ◁
#**define** *list_tag*   2   ▷ character has a successor in a charlist ◁
#**define** *ext_tag*   3   ▷ character is extensible ◁

545.   The *lig_kern* array contains instructions in a simple programming language that explains what to do for special letter pairs. Each word in this array is a *lig_kern_command* of four bytes.

first byte: *skip_byte*, indicates that this is the final program step if the byte is 128 or more, otherwise the next step is obtained by skipping this number of intervening steps.

second byte: *next_char*, "if *next_char* follows the current character, then perform the operation and stop, otherwise continue."

third byte: *op_byte*, indicates a ligature step if less than 128, a kern step otherwise.

fourth byte: *rem*.

In a kern step, an additional space equal to $kern[256*(op\_byte-128)+rem]$ is inserted between the current character and *next_char*. This amount is often negative, so that the characters are brought closer together by kerning; but it might be positive.

There are eight kinds of ligature steps, having *op_byte* codes $4a+2b+c$ where $0 \le a \le b+c$ and $0 \le b, c \le 1$. The character whose code is *rem* is inserted between the current character and *next_char*; then the current character is deleted if $b = 0$, and *next_char* is deleted if $c = 0$; then we pass over a characters to reach the next current character (which may have a ligature/kerning program of its own).

If the very first instruction of the *lig_kern* array has $skip\_byte \equiv 255$, the *next_char* byte is the so-called boundary character of this font; the value of *next_char* need not lie between *bc* and *ec*. If the very last instruction of the *lig_kern* array has $skip\_byte \equiv 255$, there is a special ligature/kerning program for a boundary character at the left, beginning at location $256 * op\_byte + rem$. The interpretation is that TeX puts implicit boundary characters before and after each consecutive string of characters from the same font. These implicit characters do not appear in the output, but they can affect ligatures and kerning.

If the very first instruction of a character's *lig_kern* program has $skip\_byte > 128$, the program actually begins in location $256 * op\_byte + rem$. This feature allows access to large *lig_kern* arrays, because the first instruction must otherwise appear in a location ≤ 255.

Any instruction with $skip\_byte > 128$ in the *lig_kern* array must satisfy the condition

$$256 * op\_byte + rem < nl.$$

If such an instruction is encountered during normal program execution, it denotes an unconditional halt; no ligature or kerning command is performed.

#**define** *stop_flag* $qi(128)$ ▷ value indicating 'STOP' in a lig/kern program ◁
#**define** *kern_flag* $qi(128)$ ▷ op code for a kern step ◁
#**define** *skip_byte*(A) *A.b0*
#**define** *next_char*(A) *A.b1*
#**define** *op_byte*(A) *A.b2*
#**define** *rem_byte*(A) *A.b3*

546.   Extensible characters are specified by an *extensible_recipe*, which consists of four bytes called *top*, *mid*, *bot*, and *rep* (in this order). These bytes are the character codes of individual pieces used to build up a large symbol. If *top*, *mid*, or *bot* are zero, they are not present in the built-up result. For example, an extensible vertical line is like an extensible bracket, except that the top and bottom pieces are missing.

Let T, M, B, and R denote the respective pieces, or an empty box if the piece isn't present. Then the extensible characters have the form $TR^k MR^k B$ from top to bottom, for some $k \ge 0$, unless M is absent; in the latter case we can have $TR^k B$ for both even and odd values of k. The width of the extensible character is the width of R; and the height-plus-depth is the sum of the individual height-plus-depths of the components used, since the pieces are butted together in a vertical list.

#**define** *ext_top*(A) *A.b0*   ▷ *top* piece in a recipe ◁
#**define** *ext_mid*(A) *A.b1*   ▷ *mid* piece in a recipe ◁
#**define** *ext_bot*(A) *A.b2*   ▷ *bot* piece in a recipe ◁
#**define** *ext_rep*(A) *A.b3*   ▷ *rep* piece in a recipe ◁

547.   The final portion of a TFM file is the *param* array, which is another sequence of *fix_word* values.

param[1] ≡ *slant* is the amount of italic slant, which is used to help position accents. For example, *slant* ≡ .25 means that when you go up one unit, you also go .25 units to the right. The *slant* is a pure number; it's the only *fix_word* other than the design size itself that is not scaled by the design size.

param[2] ≡ *space* is the normal spacing between words in text. Note that character '␣' in the font need not have anything to do with blank spaces.

param[3] ≡ *space_stretch* is the amount of glue stretching between words.

param[4] ≡ *space_shrink* is the amount of glue shrinking between words.

param[5] ≡ *x_height* is the size of one ex in the font; it is also the height of letters for which accents don't have to be raised or lowered.

param[6] ≡ *quad* is the size of one em in the font.

param[7] ≡ *extra_space* is the amount added to *param*[2] at the ends of sentences.

If fewer than seven parameters are present, TeX sets the missing parameters to zero. Fonts used for math symbols are required to have additional parameter information, which is explained later.

#**define** *slant_code*   1
#**define** *space_code*   2
#**define** *space_stretch_code*   3
#**define** *space_shrink_code*   4
#**define** *x_height_code*   5
#**define** *quad_code*   6
#**define** *extra_space_code*   7

548.   So that is what TFM files hold. Since TeX has to absorb such information about lots of fonts, it stores most of the data in a large array called *font_info*. Each item of *font_info* is a **memory_word**; the *fix_word* data gets converted into **scaled** entries, while everything else goes into words of type **four_quarters**.

When the user defines \font\f, say, TeX assigns an internal number to the user's font \f. Adding this number to *font_id_base* gives the *eqtb* location of a "frozen" control sequence that will always select the font.

⟨ Types in the outer block 18 ⟩ +≡
    typedef uint8_t internal_font_number;   ▷ *font* in a *char_node* ◁

554.   Of course we want to define macros that suppress the detail of how font information is actually packed, so that we don't have to write things like

$$font\_info[width\_base[f] + font\_info[char\_base[f] + c].qqqq.b0].sc$$

too often.   The WEB definitions here make $char\_info(f)(c)$ the **four_quarters** word of font information corresponding to character c of font f. If q is such a word, $char\_width(f)(q)$ will be the character's width; hence the long formula above is at least abbreviated to

$$char\_width(f)(char\_info(f)(c)).$$

Usually, of course, we will fetch q first and look at several of its fields at the same time.

The italic correction of a character will be denoted by $char\_italic(f)(q)$, so it is analogous to $char\_width$. But we will get at the height and depth in a slightly different way, since we usually want to compute both height and depth if we want either one. The value of $height\_depth(q)$ will be the 8-bit quantity

$$b = height\_index \times 16 + depth\_index,$$

and if b is such a byte we will write $char\_height(f)(b)$ and $char\_depth(f)(b)$ for the height and depth of the character c for which $q \equiv char\_info(f)(c)$. Got that?

The tag field will be called $char\_tag(q)$; the remainder byte will be called $rem\_byte(q)$, using a macro that we have already defined above.

Access to a character's *width*, *height*, *depth*, and *tag* fields is part of TeX's inner loop, so we want these macros to produce code that is as fast as possible under the circumstances.

#**define** $char\_info(A, B)$ $font\_info[char\_base[A] + B].qqqq$
#**define** $char\_width(A, B)$ $font\_info[width\_base[A] + B.b0].sc$
#**define** $char\_exists(A)$ $(A.b0 > min\_quarterword)$
#**define** $char\_italic(A, B)$ $font\_info[italic\_base[A] + (qo(B.b2))/4].sc$
#**define** $height\_depth(A)$ $qo(A.b1)$
#**define** $char\_height(A, B)$ $font\_info[height\_base[A] + (B)/16].sc$
#**define** $char\_depth(A, B)$ $font\_info[depth\_base[A] + (B) \% 16].sc$
#**define** $char\_tag(A)$ $((qo(A.b2)) \% 4)$

555.   The global variable $null\_character$ is set up to be a word of $char\_info$ for a character that doesn't exist. Such a word provides a convenient way to deal with erroneous situations.

⟨ Global variables 13 ⟩ +≡
  static four_quarters $null\_character$;   ▷ nonexistent character information ◁

556.   ⟨ Set initial values of key variables 21 ⟩ +≡
  $null\_character.b0 \leftarrow min\_quarterword$; $null\_character.b1 \leftarrow min\_quarterword$;
  $null\_character.b2 \leftarrow min\_quarterword$; $null\_character.b3 \leftarrow min\_quarterword$;

557.   Here are some macros that help process ligatures and kerns. We write $char\_kern(f)(j)$ to find the amount of kerning specified by kerning command j in font f. If j is the $char\_info$ for a character with a ligature/kern program, the first instruction of that program is either $i \equiv font\_info[lig\_kern\_start(f)(j)]$ or $font\_info[lig\_kern\_restart(f)(i)]$, depending on whether or not $skip\_byte(i) \le stop\_flag$.

The constant $kern\_base\_offset$ should be simplified, for Pascal compilers that do not do local optimization.

#**define** $char\_kern(A, B)$ $font\_info[kern\_base[A] + 256 * op\_byte(B) + rem\_byte(B)].sc$
#**define** $kern\_base\_offset$ $256 * (128 + min\_quarterword)$
#**define** $lig\_kern\_start(A, B)$ $lig\_kern\_base[A] + B.b3$ ▷ beginning of lig/kern program ◁
#**define** $lig\_kern\_restart(A, B)$
      $lig\_kern\_base[A] + 256 * op\_byte(B) + rem\_byte(B) + 32768 - kern\_base\_offset$

558.   Font parameters are referred to as $slant(f)$, $space(f)$, etc.

#**define** $param\_end(A)$ $param\_base[A]].sc$
#**define** $param(A)$ $font\_info[A + param\_end$
#**define** $slant$ $param(slant\_code)$ ▷ slant to the right, per unit distance upward ◁
#**define** $space$ $param(space\_code)$ ▷ normal space between words ◁
#**define** $space\_stretch$ $param(space\_stretch\_code)$ ▷ stretch between words ◁
#**define** $space\_shrink$ $param(space\_shrink\_code)$ ▷ shrink between words ◁
#**define** x_height $param(x\_height\_code)$ ▷ one ex ◁
#**define** $quad$ $param(quad\_code)$ ▷ one em ◁
#**define** $extra\_space$ $param(extra\_space\_code)$ ▷ additional space at end of sentence ◁

⟨ The em width for cur_font 558 ⟩ ≡
  $quad(cur\_font)$

This code is used in section 455.

559.   ⟨ The x-height for cur_font 559 ⟩ ≡
  $x\_height(cur\_font)$

This code is used in section 455.

560.   TeX checks the information of a `TFM` file for validity as the file is being read in, so that no further checks will be needed when typesetting is going on. The somewhat tedious subroutine that does this is called $read\_font\_info$. It has four parameters: the user font identifier u, the file name and area strings nom and $aire$, and the "at" size s. If s is negative, it's the negative of a scale factor to be applied to the design size; $s \equiv -1000$ is the normal case. Otherwise s will be substituted for the design size; in this case, s must be positive and less than 2048 pt (i.e., it must be less than 2^{27} when considered as an integer).

The subroutine opens and closes a global file variable called tfm_file. It returns the value of the internal font number that was just loaded. If an error is detected, an error message is issued and no font information is stored; $null\_font$ is returned in this case.

#**define** $abort$ **goto** bad_tfm ▷ do this when the TFM data is wrong ◁

  static internal_font_number $read\_font\_info($**pointer** $u,$ **str_number** $nom,$ **str_number** $aire,$ **scaled**
        $s)$ ▷ input a TFM file ◁
{ **int** k;   ▷ index into $font\_info$ ◁
  bool $file\_opened$;   ▷ was tfm_file successfully opened? ◁
  halfword $lf, lh, bc, ec, nw, nh, nd, ni, nl, nk, ne, np$;   ▷ sizes of subfiles ◁
  internal_font_number f;   ▷ the new font's number ◁

       "Or␣maybe␣try␣'I\\font<same␣font␣id>=<name␣of␣loaded␣font>'."$)$; $error()$; **goto** $done$;
    }
This code is used in section 566.

568.   Only the first two words of the header are needed by TEX82.

⟨ Read the TFM header 568 ⟩ ≡
  { **if** (*lh* < 2) *abort*;
    store_four_quarters(*font_check*[*f*]); *fget*; *read_sixteen*(*z*);   ▷ this rejects a negative design size ◁
    fget; *z* ← *z* ∗ °*400* + *fbyte*; *fget*; *z* ← (*z* ∗ °*20*) + (*fbyte*/°*20*);
    if (*z* < *unity*) *abort*;
    while (*lh* > 2) { *fget*; *fget*; *fget*; *fget*; *decr*(*lh*);   ▷ ignore the rest of the header ◁
    }
    font_dsize[*f*] ← *z*;
    if (*s* ≠ −1000)
      if (*s* ≥ 0) *z* ← *s*;
      else *z* ← *xn_over_d*(*z*, −*s*, 1000);
    font_size[*f*] ← *z*;
  }

This code is used in section 562.

569.   ⟨ Read character data 569 ⟩ ≡
  for (*k* ← *fmem_ptr*; *k* ≤ *width_base*[*f*] − 1; *k*++) { *store_four_quarters*(*font_info*[*k*].*qqqq*);
    if ((*a* ≥ *nw*) ∨ (*b*/°*20* ≥ *nh*) ∨ (*b* % °*20* ≥ *nd*) ∨ (*c*/4 ≥ *ni*)) *abort*;
    switch (*c* % 4) {
    case *lig_tag*:
      if (*d* ≥ *nl*) *abort*; **break**;
    case *ext_tag*:
      if (*d* ≥ *ne*) *abort*; **break**;
    case *list_tag*: ⟨ Check for charlist cycle 570 ⟩ **break**;
    default: *do_nothing*;   ▷ *no_tag* ◁
    }
  }

This code is used in section 562.

570.   We want to make sure that there is no cycle of characters linked together by *list_tag* entries, since such a cycle would get TEX into an endless loop. If such a cycle exists, the routine here detects it when processing the largest character code in the cycle.

#**define** *check_byte_range*(*A*)
        { **if** ((*A* < *bc*) ∨ (*A* > *ec*)) *abort*; }
#**define** *current_character_being_worked_on*   *k* + *bc* − *fmem_ptr*

⟨ Check for charlist cycle 570 ⟩ ≡
  { *check_byte_range*(*d*);
    while (*d* < *current_character_being_worked_on*) { *qw* ← *char_info*(*f*, *d*);
        ▷ N.B.: not *qi*(*d*), since *char_base*[*f*] hasn't been adjusted yet ◁
      if (*char_tag*(*qw*) ≠ *list_tag*) **goto** *not_found*;
      d ← *qo*(*rem_byte*(*qw*));   ▷ next character on the list ◁
    }
    if (*d* ≡ *current_character_being_worked_on*) *abort*;   ▷ yes, there's a cycle ◁
  not_found: ;
  }

This code is used in section 569.

571.   A *fix_word* whose four bytes are (a, b, c, d) from left to right represents the number

$$x = \begin{cases} b \cdot 2^{-4} + c \cdot 2^{-12} + d \cdot 2^{-20}, & \text{if } a = 0; \\ -16 + b \cdot 2^{-4} + c \cdot 2^{-12} + d \cdot 2^{-20}, & \text{if } a = 255. \end{cases}$$

(No other choices of a are allowed, since the magnitude of a number in design-size units must be less than 16.) We want to multiply this quantity by the integer z, which is known to be less than 2^{27}. If $z < 2^{23}$, the individual multiplications $b \cdot z$, $c \cdot z$, $d \cdot z$ cannot overflow; otherwise we will divide z by 2, 4, 8, or 16, to obtain a multiplier less than 2^{23}, and we can compensate for this later. If z has thereby been replaced by $z' = z/2^e$, let $\beta = 2^{4-e}$; we shall compute

$$\lfloor (b + c \cdot 2^{-8} + d \cdot 2^{-16}) \, z'/\beta \rfloor$$

if $a = 0$, or the same quantity minus $\alpha = 2^{4+e} z'$ if $a = 255$. This calculation must be done exactly, in order to guarantee portability of TeX between computers.

#**define** *store_scaled*(*A*)
      { *fget*; $a \leftarrow$ *fbyte*; *fget*; $b \leftarrow$ *fbyte*; *fget*; $c \leftarrow$ *fbyte*; *fget*; $d \leftarrow$ *fbyte*;
        $sw \leftarrow (((((d * z)/°400) + (c * z))/°400) + (b * z))/beta$;
        if $(a \equiv 0)$ $A \leftarrow sw$; **else if** $(a \equiv 255)$ $A \leftarrow sw - alpha$; **else** *abort*;
      }

⟨Read box dimensions 571⟩ ≡
  { ⟨Replace z by z' and compute α, β 572⟩;

      }
      else { $print\_err($"Missing␣font␣identifier"$)$;
        $help2($"I␣was␣looking␣for␣a␣control␣sequence␣whose"$,$
        "current␣meaning␣has␣been␣defined␣by␣\\font."$)$; $back\_error()$; $f \leftarrow null\_font$;
      }
      $cur\_val \leftarrow f$;
    }
See also section 578.

This code is used in section 409.

578.   The following routine is used to implement '`\fontdimen` n f'. The boolean parameter *writing* is set *true* if the calling program intends to change the parameter value.

⟨ Declare procedures that scan font-related stuff 577 ⟩ +≡

  static void *find_font_dimen*(**bool** *writing*)　　▷ sets *cur_val* to *font_info* location ◁

  { **internal_font_number** *f*;

    int *n*;　　▷ the parameter number ◁

    scan_int( ); *n* ← *cur_val*; *scan_font_ident*( ); *f* ← *cur_val*;

    if ($n \leq 0$) *cur_val* ← *fmem_ptr*;

    else { **if** (*writing* ∧ ($n \leq$ *space_shrink_code*) ∧ ($n \geq$ *space_code*) ∧ (*font_glue*[*f*] ≠ *null*)) {

        delete_glue_ref(*font_glue*[*f*]); *font_glue*[*f*] ← *null*;

      }

      if ($n >$ *font_params*[*f*])

        if ($f <$ *font_ptr*) *cur_val* ← *fmem_ptr*;

        else ⟨ Increase the number of parameters in the last font 580 ⟩

      else *cur_val* ← n + *param_base*[*f*];

    }

    ⟨ Issue an error message if *cur_val* ← *fmem_ptr* 579 ⟩;

  }

579.   ⟨ Issue an error message if *cur_val* ← *fmem_ptr* 579 ⟩ ≡

  if (*cur_val* ≡ *fmem_ptr*) { *print_err*("`Font `"); *printn_esc*(*font_id_text*(*f*)); *print*("` has only `");

    print_int(*font_params*[*f*]); *print*("` fontdimen parameters`");

    help2("`To increase the number of font parameters, you must`",

    "`use \\fontdimen immediately after the \\font is loaded.`"); *error*( );

  }

This code is used in section 578.

580.   ⟨ Increase the number of parameters in the last font 580 ⟩ ≡

  { **do** {

    if (*fmem_ptr* ≡ *font_mem_size*) *overflow*("`font memory`", *font_mem_size*);

    font_info[*fmem_ptr*].*sc* ← 0; *incr*(*fmem_ptr*); *incr*(*font_params*[*f*]);

    } **while** (¬(*n* ≡ *font_params*[*f*]));

    cur_val ← *fmem_ptr* − 1;　　▷ this equals *param_base*[*f*] + *font_params*[*f*] ◁

  }

This code is used in section 578.

581.   When TeX wants to typeset a character that doesn't exist, the character node is not created; thus the output routine can assume that characters exist when it sees them. The following procedure prints a warning message unless the user has suppressed it.

  static void *char_warning*(**internal_font_number** *f*, **eight_bits** *c*)

  { **int** *old_setting*;　　▷ saved value of *tracing_online* ◁

    if (*tracing_lost_chars* > 0) { *old_setting* ← *tracing_online*;

      if (*eTeX_ex* ∧ (*tracing_lost_chars* > 1)) *tracing_online* ← 1;

      { *begin_diagnostic*( ); *print_nl*("`Missing character: There is no `"); *print_ASCII*(*c*);

        print("` in font `"); *slow_print*(*font_name*[*f*]); *print_char*('!'); *end_diagnostic*(*false*);

      }

      tracing_online ← *old_setting*;

    }

  }

582. Here is a function that returns a pointer to a character node for a given character in a given font. If that character doesn't exist, *null* is returned instead.

static pointer *new_character* (**internal_font_number** f, **eight_bits** c)
{ **pointer** p;   ▷ newly allocated node ◁

  if $(font\_bc[f] \leq c)$
    if $(font\_ec[f] \geq c)$
      if $(char\_exists(char\_info(f, qi(c))))$ { $p \leftarrow get\_avail()$; $font(p) \leftarrow f$; $character(p) \leftarrow qi(c)$;
        return p;
      }
  char_warning (f, c); **return** *null*;
}

583.   Device-independent file format.   The most important output produced by a run of TEX is the "device independent" (`DVI`) file that specifies where characters and rules are to appear on printed pages. The form of these files was designed by David R. Fuchs in 1979. Almost any reasonable typesetting device can be driven by a program that takes `DVI` files as input, and dozens of such `DVI`-to-whatever programs have been written. Thus, it is possible to print the output of TEX on many different kinds of equipment, using TEX as a device-independent "front end."

A `DVI` file is a stream of 8-bit bytes, which may be regarded as a series of commands in a machine-like language. The first byte of each command is the operation code, and this code is followed by zero or more bytes that provide parameters to the command. The parameters themselves may consist of several consecutive bytes; for example, the '*set_rule*' command has two parameters, each of which is four bytes long. Parameters are usually regarded as nonnegative integers; but four-byte-long parameters, and shorter parameters that denote distances, can be either positive or negative. Such parameters are given in two's complement notation. For example, a two-byte-long distance parameter has a value between -2^{15} and $2^{15} - 1$. As in `TFM` files, numbers that occupy more than one byte position appear in BigEndian order.

A `DVI` file consists of a "preamble," followed by a sequence of one or more "pages," followed by a "postamble." The preamble is simply a *pre* command, with its parameters that define the dimensions used in the file; this must come first. Each "page" consists of a *bop* command, followed by any number of other commands that tell where characters are to be placed on a physical page, followed by an *eop* command. The pages appear in the order that TEX generated them. If we ignore *nop* commands and *fnt_def* commands (which are allowed between any two commands in the file), each *eop* command is immediately followed by a *bop* command, or by a *post* command; in the latter case, there are no more pages in the file, and the remaining bytes form the postamble. Further details about the postamble will be explained later.

Some parameters in `DVI` commands are "pointers." These are four-byte quantities that give the location number of some other byte in the file; the first byte is number 0, then comes number 1, and so on. For example, one of the parameters of a *bop* command points to the previous *bop*; this makes it feasible to read the pages in backwards order, in case the results are being directed to a device that stacks its output face up. Suppose the preamble of a `DVI` file occupies bytes 0 to 99. Now if the first page occupies bytes 100 to 999, say, and if the second page occupies bytes 1000 to 1999, then the *bop* that starts in byte 1000 points to 100 and the *bop* that starts in byte 2000 points to 1000. (The very first *bop*, i.e., the one starting in byte 100, has a pointer of -1.)

584.   The `DVI` format is intended to be both compact and easily interpreted by a machine. Compactness is achieved by making most of the information implicit instead of explicit. When a `DVI`-reading program reads the commands for a page, it keeps track of several quantities: (a) The current font f is an integer; this value is changed only by *fnt* and *fnt_num* commands. (b) The current position on the page is given by two numbers called the horizontal and vertical coordinates, h and v. Both coordinates are zero at the upper left corner of the page; moving to the right corresponds to increasing the horizontal coordinate, and moving down corresponds to increasing the vertical coordinate. Thus, the coordinates are essentially Cartesian, except that vertical directions are flipped; the Cartesian version of (h, v) would be $(h, -v)$. (c) The current spacing amounts are given by four numbers w, x, y, and z, where w and x are used for horizontal spacing and where y and z are used for vertical spacing. (d) There is a stack containing (h, v, w, x, y, z) values; the `DVI` commands *push* and *pop* are used to change the current level of operation. Note that the current font f is not pushed and popped; the stack contains only information about positioning.

The values of h, v, w, x, y, and z are signed integers having up to 32 bits, including the sign. Since they represent physical distances, there is a small unit of measurement such that increasing h by 1 means moving a certain tiny distance to the right. The actual unit of measurement is variable, as explained below; TEX sets things up so that its `DVI` output is in sp units, i.e., scaled points, in agreement with all the **scaled** dimensions in TEX's data structures.

585. Here is a list of all the commands that may appear in a DVI file. Each command is specified by its symbolic name (e.g., *bop*), its opcode byte (e.g., 139), and its parameters (if any). The parameters are followed by a bracketed number telling how many bytes they occupy; for example, '$p[4]$' means that parameter p is four bytes long.

set_char_0 0. Typeset character number 0 from font f such that the reference point of the character is at (h, v). Then increase h by the width of that character. Note that a character may have zero or negative width, so one cannot be sure that h will advance after this command; but h usually does increase.

set_char_1 through *set_char_127* (opcodes 1 to 127). Do the operations of *set_char_0*; but use the character whose number matches the opcode, instead of character 0.

set1 128 $c[1]$. Same as *set_char_0*, except that character number c is typeset. TeX82 uses this command for characters in the range $128 \leq c < 256$.

set2 129 $c[2]$. Same as *set1*, except that c is two bytes long, so it is in the range $0 \leq c < 65536$. TeX82 never uses this command, but it should come in handy for extensions of TeX that deal with oriental languages.

set3 130 $c[3]$. Same as *set1*, except that c is three bytes long, so it can be as large as $2^{24} - 1$. Not even the Chinese language has this many characters, but this command might prove useful in some yet unforeseen extension.

set4 131 $c[4]$. Same as *set1*, except that c is four bytes long. Imagine that.

set_rule 132 $a[4]$ $b[4]$. Typeset a solid black rectangle of height a and width b, with its bottom left corner at (h, v). Then set $h \leftarrow h + b$. If either $a \leq 0$ or $b \leq 0$, nothing should be typeset. Note that if $b < 0$, the value of h will decrease even though nothing else happens. See below for details about how to typeset rules so that consistency with METAFONT is guaranteed.

put1 133 $c[1]$. Typeset character number c from font f such that the reference point of the character is at (h, v). (The 'put' commands are exactly like the 'set' commands, except that they simply put out a character or a rule without moving the reference point afterwards.)

put2 134 $c[2]$. Same as *set2*, except that h is not changed.

put3 135 $c[3]$. Same as *set3*, except that h is not changed.

put4 136 $c[4]$. Same as *set4*, except that h is not changed.

put_rule 137 $a[4]$ $b[4]$. Same as *set_rule*, except that h is not changed.

nop 138. No operation, do nothing. Any number of *nop*'s may occur between DVI commands, but a *nop* cannot be inserted between a command and its parameters or between two parameters.

bop 139 $c_0[4]$ $c_1[4]$ ... $c_9[4]$ $p[4]$. Beginning of a page: Set $(h, v, w, x, y, z) \leftarrow (0, 0, 0, 0, 0, 0)$ and set the stack empty. Set the current font f to an undefined value. The ten c_i parameters hold the values of \count0 ... \count9 in TeX at the time \shipout was invoked for this page; they can be used to identify pages, if a user wants to print only part of a DVI file. The parameter p points to the previous *bop* in the file; the first *bop* has $p = -1$.

eop 140. End of page: Print what you have read since the previous *bop*. At this point the stack should be empty. (The DVI-reading programs that drive most output devices will have kept a buffer of the material that appears on the page that has just ended. This material is largely, but not entirely, in order by v coordinate and (for fixed v) by h coordinate; so it usually needs to be sorted into some order that is appropriate for the device in question.)

push 141. Push the current values of (h, v, w, x, y, z) onto the top of the stack; do not change any of these values. Note that f is not pushed.

pop 142. Pop the top six values off of the stack and assign them respectively to (h, v, w, x, y, z). The number of pops should never exceed the number of pushes, since it would be highly embarrassing if the stack were empty at the time of a *pop* command.

right1 143 $b[1]$. Set $h \leftarrow h+b$, i.e., move right b units. The parameter is a signed number in two's complement notation, $-128 \le b < 128$; if $b < 0$, the reference point moves left.

right2 144 $b[2]$. Same as *right1*, except that b is a two-byte quantity in the range $-32768 \le b < 32768$.

right3 145 $b[3]$. Same as *right1*, except that b is a three-byte quantity in the range $-2^{23} \le b <$.

right4 146 $b[4]$. Same as *right1*, except that b is a four-byte quantity in the range $-2^{31} \le b <$.

w0 147. Set $h \leftarrow h+w$; i.e., move right w units. With luck, this parameterless command will usually suffice, because the same kind of motion will occur several times in succession; the following commands explain how w gets particular values.

w1 148 $b[1]$. Set $w \leftarrow b$ and $h \leftarrow h + b$. The value of b is a signed quantity in two's complement notation, $-128 \le b < 128$. This command changes the current w spacing and moves right by b.

w2 149 $b[2]$. Same as *w1*, but b is two bytes long, $-32768 \le b < 32768$.

w3 150 $b[3]$. Same as *w1*, but b is three bytes long, $-2^{23} \le b <$.

w4 151 $b[4]$. Same as *w1*, but b is four bytes long, $-2^{31} \le b <$.

x0 152. Set $h \leftarrow h + x$; i.e., move right x units. The 'x' commands are like the 'w' commands except that they involve x instead of w.

x1 153 $b[1]$. Set $x \leftarrow b$ and $h \leftarrow h + b$. The value of b is a signed quantity in two's complement notation, $-128 \le b < 128$. This command changes the current x spacing and moves right by b.

x2 154 $b[2]$. Same as *x1*, but b is two bytes long, $-32768 \le b < 32768$.

x3 155 $b[3]$. Same as *x1*, but b is three bytes long, $-2^{23} \le b <$.

x4 156 $b[4]$. Same as *x1*, but b is four bytes long, $-2^{31} \le b <$.

down1 157 $a[1]$. Set $v \leftarrow v + a$, i.e., move down a units. The parameter is a signed number in two's complement notation, $-128 \le a < 128$; if $a < 0$, the reference point moves up.

down2 158 $a[2]$. Same as *down1*, except that a is a two-byte quantity in the range $-32768 \le a < 32768$.

down3 159 $a[3]$. Same as *down1*, except that a is a three-byte quantity in the range $-2^{23} \le a <$.

down4 160 $a[4]$. Same as *down1*, except that a is a four-byte quantity in the range $-2^{31} \le a <$.

y0 161. Set $v \leftarrow v + y$; i.e., move down y units. With luck, this parameterless command will usually suffice, because the same kind of motion will occur several times in succession; the following commands explain how y gets particular values.

y1 162 $a[1]$. Set $y \leftarrow a$ and $v \leftarrow v + a$. The value of a is a signed quantity in two's complement notation, $-128 \le a < 128$. This command changes the current y spacing and moves down by a.

y2 163 $a[2]$. Same as *y1*, but a is two bytes long, $-32768 \le a < 32768$.

y3 164 $a[3]$. Same as *y1*, but a is three bytes long, $-2^{23} \le a <$.

y4 165 $a[4]$. Same as *y1*, but a is four bytes long, $-2^{31} \le a <$.

z0 166. Set $v \leftarrow v + z$; i.e., move down z units. The 'z' commands are like the 'y' commands except that they involve z instead of y.

z1 167 $a[1]$. Set $z \leftarrow a$ and $v \leftarrow v + a$. The value of a is a signed quantity in two's complement notation, $-128 \le a < 128$. This command changes the current z spacing and moves down by a.

z2 168 $a[2]$. Same as *z1*, but a is two bytes long, $-32768 \le a < 32768$.

z3 169 $a[3]$. Same as *z1*, but a is three bytes long, $-2^{23} \le a <$.

z4 170 $a[4]$. Same as *z1*, but a is four bytes long, $-2^{31} \le a <$.

fnt_num_0 171. Set $f \leftarrow 0$. Font 0 must previously have been defined by a *fnt_def* instruction, as explained below.

fnt_num_1 through *fnt_num_63* (opcodes 172 to 234). Set $f \leftarrow 1, \ldots, f \leftarrow 63$, respectively.

fnt1 235 $k[1]$. Set $f \leftarrow k$. TeX82 uses this command for font numbers in the range $64 \le k < 256$.

fnt2 236 $k[2]$. Same as *fnt1*, except that k is two bytes long, so it is in the range $0 \leq k < 65536$. TEX82 never generates this command, but large font numbers may prove useful for specifications of color or texture, or they may be used for special fonts that have fixed numbers in some external coding scheme.

fnt3 237 $k[3]$. Same as *fnt1*, except that k is three bytes long, so it can be as large as $2^{24} - 1$.

fnt4 238 $k[4]$. Same as *fnt1*, except that k is four bytes long; this is for the really big font numbers (and for the negative ones).

xxx1 239 $k[1]$ $x[k]$. This command is undefined in general; it functions as a $(k + 2)$-byte *nop* unless special DVI-reading programs are being used. TEX82 generates *xxx1* when a short enough `\special` appears, setting k to the number of bytes being sent. It is recommended that x be a string having the form of a keyword followed by possible parameters relevant to that keyword.

xxx2 240 $k[2]$ $x[k]$. Like *xxx1*, but $0 \leq k < 65536$.

xxx3 241 $k[3]$ $x[k]$. Like *xxx1*, but $0 \leq k <$.

xxx4 242 $k[4]$ $x[k]$. Like *xxx1*, but k can be ridiculously large. TEX82 uses *xxx4* when sending a string of length 256 or more.

fnt_def1 243 $k[1]$ $c[4]$ $s[4]$ $d[4]$ $a[1]$ $l[1]$ $n[a + l]$. Define font k, where $0 \leq k < 256$; font definitions will be explained shortly.

fnt_def2 244 $k[2]$ $c[4]$ $s[4]$ $d[4]$ $a[1]$ $l[1]$ $n[a + l]$. Define font k, where $0 \leq k < 65536$.

fnt_def3 245 $k[3]$ $c[4]$ $s[4]$ $d[4]$ $a[1]$ $l[1]$ $n[a + l]$. Define font k, where $0 \leq k <$.

fnt_def4 246 $k[4]$ $c[4]$ $s[4]$ $d[4]$ $a[1]$ $l[1]$ $n[a + l]$. Define font k, where $-2^{31} \leq k <$.

pre 247 $i[1]$ $num[4]$ $den[4]$ $mag[4]$ $k[1]$ $x[k]$. Beginning of the preamble; this must come at the very beginning of the file. Parameters i, num, den, mag, k, and x are explained below.

post 248. Beginning of the postamble, see below.

post_post 249. Ending of the postamble, see below.

Commands 250–255 are undefined at the present time.

587.   The preamble contains basic information about the file as a whole. As stated above, there are six parameters:

$$i[1]\ num[4]\ den[4]\ mag[4]\ k[1]\ x[k].$$

The i byte identifies DVI format; currently this byte is always set to 2. (The value $i \equiv 3$ is currently used for an extended format that allows a mixture of right-to-left and left-to-right typesetting. Some day we will set $i \equiv 4$, when DVI format makes another incompatible change—perhaps in the year 2048.)

The next two parameters, *num* and *den*, are positive integers that define the units of measurement; they are the numerator and denominator of a fraction by which all dimensions in the DVI file could be multiplied in order to get lengths in units of 10^{-7} meters. Since 7227pt = 254cm, and since TeX works with scaled points where there are 2^{16} sp in a point, TeX sets $num/den = (254 \cdot 10^5)/(7227 \cdot 2^{16}) = 25400000/473628672$.

The *mag* parameter is what TeX calls \mag, i.e., 1000 times the desired magnification. The actual fraction by which dimensions are multiplied is therefore $mag \cdot num/1000den$. Note that if a TeX source document does not call for any 'true' dimensions, and if you change it only by specifying a different \mag setting, the DVI file that TeX creates will be completely unchanged except for the value of *mag* in the preamble and postamble. (Fancy DVI-reading programs allow users to override the *mag* setting when a DVI file is being printed.)

Finally, k and x allow the DVI writer to include a comment, which is not interpreted further. The length of comment x is k, where $0 \le k < 256$.

#**define** *id_byte*   2   ▷ identifies the kind of DVI files described here ◁

588.   Font definitions for a given font number k contain further parameters

$$c[4]\ s[4]\ d[4]\ a[1]\ l[1]\ n[a+l].$$

The four-byte value c is the check sum that TeX found in the `TFM` file for this font; c should match the check sum of the font found by programs that read this `DVI` file.

Parameter s contains a fixed-point scale factor that is applied to the character widths in font k; font dimensions in `TFM` files and other font files are relative to this quantity, which is called the "at size" elsewhere in this documentation. The value of s is always positive and less than 2^{27}. It is given in the same units as the other `DVI` dimensions, i.e., in sp when TeX82 has made the file. Parameter d is similar to s; it is the "design size," and (like s) it is given in `DVI` units. Thus, font k is to be used at $mag \cdot s/1000d$ times its normal size.

The remaining part of a font definition gives the external name of the font, which is an ASCII string of length $a+l$. The number a is the length of the "area" or directory, and l is the length of the font name itself; the standard local system font area is supposed to be used when $a \equiv 0$. The n field contains the area in its first a bytes.

Font definitions must appear before the first use of a particular font number. Once font k is defined, it must not be defined again; however, we shall see below that font definitions appear in the postamble as well as in the pages, so in this sense each font number is defined exactly twice, if at all. Like *nop* commands, font definitions can appear before the first *bop*, or between an *eop* and a *bop*.

589.   Sometimes it is desirable to make horizontal or vertical rules line up precisely with certain features in characters of a font. It is possible to guarantee the correct matching between `DVI` output and the characters generated by METAFONT by adhering to the following principles: (1) The METAFONT characters should be positioned so that a bottom edge or left edge that is supposed to line up with the bottom or left edge of a rule appears at the reference point, i.e., in row 0 and column 0 of the METAFONT raster. This ensures that the position of the rule will not be rounded differently when the pixel size is not a perfect multiple of the units of measurement in the `DVI` file. (2) A typeset rule of height $a > 0$ and width $b > 0$ should be equivalent to a METAFONT-generated character having black pixels in precisely those raster positions whose METAFONT coordinates satisfy $0 \le x < \alpha b$ and $0 \le y < \alpha a$, where α is the number of pixels per `DVI` unit.

590.   The last page in a `DVI` file is followed by '*post*'; this command introduces the postamble, which summarizes important facts that TeX has accumulated about the file, making it possible to print subsets of the data with reasonable efficiency. The postamble has the form

$$post\ p[4]\ num[4]\ den[4]\ mag[4]\ l[4]\ u[4]\ s[2]\ t[2]$$
$$\langle\, font\ definitions\,\rangle$$
$$post\_post\ q[4]\ i[1]\ 223\text{'s}[{\ge}4]$$

Here p is a pointer to the final *bop* in the file. The next three parameters, *num*, *den*, and *mag*, are duplicates of the quantities that appeared in the preamble.

Parameters l and u give respectively the height-plus-depth of the tallest page and the width of the widest page, in the same units as other dimensions of the file. These numbers might be used by a `DVI`-reading program to position individual "pages" on large sheets of film or paper; however, the standard convention for output on normal size paper is to position each page so that the upper left-hand corner is exactly one inch from the left and the top. Experience has shown that it is unwise to design `DVI`-to-printer software that attempts cleverly to center the output; a fixed position of the upper left corner is easiest for users to understand and to work with. Therefore l and u are often ignored.

Parameter s is the maximum stack depth (i.e., the largest excess of *push* commands over *pop* commands) needed to process this file. Then comes t, the total number of pages (*bop* commands) present.

The postamble continues with font definitions, which are any number of *fnt_def* commands as described above, possibly interspersed with *nop* commands. Each font number that is used in the `DVI` file must be defined exactly twice: Once before it is first selected by a *fnt* command, and once in the postamble.

591.   The last part of the postamble, following the *post_post* byte that signifies the end of the font definitions, contains q, a pointer to the *post* command that started the postamble. An identification byte, i, comes next; this currently equals 2, as in the preamble.

The i byte is followed by four or more bytes that are all equal to the decimal number 223 (i.e., 0337 in octal). TeX puts out four to seven of these trailing bytes, until the total length of the file is a multiple of four bytes, since this works out best on machines that pack four bytes per word; but any number of 223's is allowed, as long as there are at least four of them. In effect, 223 is a sort of signature that is added at the very end.

This curious way to finish off a DVI file makes it feasible for DVI-reading programs to find the postamble first, on most computers, even though TeX wants to write the postamble last. Most operating systems permit random access to individual words or bytes of a file, so the DVI reader can start at the end and skip backwards over the 223's until finding the identification byte. Then it can back up four bytes, read q, and move to byte q of the file. This byte should, of course, contain the value 248 (*post*); now the postamble can be read, so the DVI reader can discover all the information needed for typesetting the pages. Note that it is also possible to skip through the DVI file at reasonably high speed to locate a particular page, if that proves desirable. This saves a lot of time, since DVI files used in production jobs tend to be large.

Unfortunately, however, standard Pascal does not include the ability to access a random position in a file, or even to determine the length of a file. Almost all systems nowadays provide the necessary capabilities, so DVI format has been designed to work most efficiently with modern operating systems. But if DVI files have to be processed under the restrictions of standard Pascal, one can simply read them from front to back, since the necessary header information is present in the preamble and in the font definitions. (The l and u and s and t parameters, which appear only in the postamble, are "frills" that are handy but not absolutely necessary.)

592. Shipping pages out.   After considering TeX's eyes and stomach, we come now to the bowels.

The *ship_out* procedure is given a pointer to a box; its mission is to describe that box in DVI form, outputting a "page" to *dvi_file*. The DVI coordinates $(h, v) = (0,0)$ should correspond to the upper left corner of the box being shipped.

Since boxes can be inside of boxes inside of boxes, the main work of *ship_out* is done by two mutually recursive routines, *hlist_out* and *vlist_out*, which traverse the hlists and vlists inside of horizontal and vertical boxes.

As individual pages are being processed, we need to accumulate information about the entire set of pages, since such statistics must be reported in the postamble. The global variables *total_pages*, *max_v*, *max_h*, *max_push*, and *last_bop* are used to record this information.

The variable *doing_leaders* is *true* while leaders are being output. The variable *dead_cycles* contains the number of times an output routine has been initiated since the last *ship_out*.

A few additional global variables are also defined here for use in *vlist_out* and *hlist_out*. They could have been local variables, but that would waste stack space when boxes are deeply nested, since the values of these variables are not needed during recursive calls.

⟨ Global variables 13 ⟩ +≡
    static int *total_pages*;   ▷ the number of pages that have been shipped out ◁
    static scaled *max_v*;   ▷ maximum height-plus-depth of pages shipped so far ◁
    static scaled *max_h*;   ▷ maximum width of pages shipped so far ◁
    static int *max_push*;   ▷ deepest nesting of *push* commands encountered so far ◁
    static int *last_bop*;   ▷ location of previous *bop* in the DVI output ◁
    static int *dead_cycles*;   ▷ recent outputs that didn't ship anything out ◁
    static bool *doing_leaders*;   ▷ are we inside a leader box? ◁
    static quarterword c, f;   ▷ character and font in current *char_node* ◁
    static scaled *rule_ht*, *rule_dp*, *rule_wd*;   ▷ size of current rule being output ◁
    static pointer g;   ▷ current glue specification ◁
    static int *lq*, *lr*;   ▷ quantities used in calculations for leaders ◁

593.   ⟨ Set initial values of key variables 21 ⟩ +≡
    $total\_pages \leftarrow 0$; $max\_v \leftarrow 0$; $max\_h \leftarrow 0$; $max\_push \leftarrow 0$; $last\_bop \leftarrow -1$; $doing\_leaders \leftarrow false$;
    $dead\_cycles \leftarrow 0$; $cur\_s \leftarrow -1$;

594.   The DVI bytes are output to a buffer instead of being written directly to the output file. This makes it possible to reduce the overhead of subroutine calls, thereby measurably speeding up the computation, since output of DVI bytes is part of TeX's inner loop. And it has another advantage as well, since we can change instructions in the buffer in order to make the output more compact. For example, a '*down2*' command can be changed to a '*y2*', thereby making a subsequent '*y0*' command possible, saving two bytes.

The output buffer is divided into two parts of equal size; the bytes found in *dvi_buf* [0 .. *half_buf* − 1] constitute the first half, and those in *dvi_buf* [*half_buf* .. *dvi_buf_size* − 1] constitute the second. The global variable *dvi_ptr* points to the position that will receive the next output byte. When *dvi_ptr* reaches *dvi_limit*, which is always equal to one of the two values *half_buf* or *dvi_buf_size*, the half buffer that is about to be invaded next is sent to the output and *dvi_limit* is changed to its other value. Thus, there is always at least a half buffer's worth of information present, except at the very beginning of the job.

Bytes of the DVI file are numbered sequentially starting with 0; the next byte to be generated will be number *dvi_offset* + *dvi_ptr*. A byte is present in the buffer only if its number is ≥ *dvi_gone*.

⟨ Types in the outer block 18 ⟩ +≡
    typedef int16_t dvi_index;   ▷ an index into the output buffer ◁

595.   Some systems may find it more efficient to make dvi_buf a array, since output of four bytes at once may be facilitated.

⟨Global variables 13⟩ +≡

  static eight_bits $dvi\_buf[dvi\_buf\_size + 1]$;   ▷ buffer for DVI output ◁

  static dvi_index $half\_buf$;   ▷ half of dvi_buf_size ◁

  static dvi_index dvi_limit;   ▷ end of the current half buffer ◁

  static dvi_index dvi_ptr;   ▷ the next available buffer address ◁

  static int dvi_offset;   ▷ dvi_buf_size times the number of times the output buffer has been fully emptied ◁

  static int dvi_gone;   ▷ the number of bytes already output to dvi_file ◁

596.   Initially the buffer is all in one piece; we will output half of it only after it first fills up.

⟨Set initial values of key variables 21⟩ +≡

  $half\_buf \leftarrow dvi\_buf\_size/2$; $dvi\_limit \leftarrow dvi\_buf\_size$; $dvi\_ptr \leftarrow 0$; $dvi\_offset \leftarrow 0$; $dvi\_gone \leftarrow 0$;

597.   The actual output of $dvi\_buf[a \mathinner{.\,.} b]$ to dvi_file is performed by calling $write\_dvi(a, b)$. For best results, this procedure should be optimized to run as fast as possible on each particular system, since it is part of TEX's inner loop. It is safe to assume that a and $b+1$ will both be multiples of 4 when $write\_dvi(a, b)$ is called; therefore it is possible on many machines to use efficient methods to pack four bytes per word and to output an array of words with one system call.

  static void $write\_dvi(\textbf{dvi\_index}\ a, \textbf{dvi\_index}\ b)$

  { **int** k;

    for $(k \leftarrow a;\ k \leq b;\ k{+}{+})\ pascal\_write(dvi\_file, \texttt{"\%c"}, dvi\_buf[k])$;

  }

598.   To put a byte in the buffer without paying the cost of invoking a procedure each time, we use the macro dvi_out.

#define $dvi\_out(A)$ { $dvi\_buf[dvi\_ptr] \leftarrow A$; $incr(dvi\_ptr)$;

        if $(dvi\_ptr \equiv dvi\_limit)\ dvi\_swap(\,)$;

      }

  static void $dvi\_swap(\textbf{void})$ ▷ outputs half of the buffer ◁

  { **if** $(dvi\_limit \equiv dvi\_buf\_size)$ { $write\_dvi(0, half\_buf - 1)$; $dvi\_limit \leftarrow half\_buf$;

    $dvi\_offset \leftarrow dvi\_offset + dvi\_buf\_size$; $dvi\_ptr \leftarrow 0$;

    }

    else { $write\_dvi(half\_buf, dvi\_buf\_size - 1)$; $dvi\_limit \leftarrow dvi\_buf\_size$;

    }

    $dvi\_gone \leftarrow dvi\_gone + half\_buf$;

  }

599.   Here is how we clean out the buffer when TEX is all through; dvi_ptr will be a multiple of 4.

⟨Empty the last bytes out of dvi_buf 599⟩ ≡

  if $(dvi\_limit \equiv half\_buf)\ write\_dvi(half\_buf, dvi\_buf\_size - 1)$;

  if $(dvi\_ptr > 0)\ write\_dvi(0, dvi\_ptr - 1)$

This code is used in section 642.

600.   The *dvi_four* procedure outputs four bytes in two's complement notation, without risking arithmetic overflow.

```
static void dvi_four(int x)
{ if (x ≥ 0) dvi_out(x/°100000000)
  else { x ← x + °10000000000; x ← x + °10000000000; dvi_out((x/°100000000) + 128);
  }
  x ← x % °100000000; dvi_out(x/°200000); x ← x % °200000; dvi_out(x/°400); dvi_out(x % °400);
}
```

601.   A mild optimization of the output is performed by the *dvi_pop* routine, which issues a *pop* unless it is possible to cancel a '*push pop*' pair. The parameter to *dvi_pop* is the byte address following the old *push* that matches the new *pop*.

```
static void dvi_pop(int l)
{ if ((l ≡ dvi_offset + dvi_ptr) ∧ (dvi_ptr > 0)) decr(dvi_ptr);
  else dvi_out(pop);
}
```

602.   Here's a procedure that outputs a font definition. Since TeX82 uses at most 256 different fonts per job, *fnt_def1* is always used as the command code.

```
static void dvi_font_def(internal_font_number f)
{ int k;      ▷ index into str_pool ◁

  dvi_out(fnt_def1); dvi_out(f − font_base − 1);
  dvi_out(qo(font_check[f].b0)); dvi_out(qo(font_check[f].b1)); dvi_out(qo(font_check[f].b2));
  dvi_out(qo(font_check[f].b3));
  dvi_four(font_size[f]); dvi_four(font_dsize[f]);
  dvi_out(length(font_area[f])); dvi_out(length(font_name[f]));
  ⟨Output the font name whose internal number is f 603⟩;
}
```

603.   ⟨Output the font name whose internal number is f 603⟩ ≡
　for (k ← str_start[font_area[f]]; k ≤ str_start[font_area[f] + 1] − 1; k++) dvi_out(so(str_pool[k]));
　for (k ← str_start[font_name[f]]; k ≤ str_start[font_name[f] + 1] − 1; k++) dvi_out(so(str_pool[k]))

This code is used in section 602.

604. Versions of TeX intended for small computers might well choose to omit the ideas in the next few parts of this program, since it is not really necessary to optimize the DVI code by making use of the $w0$, $x0$, $y0$, and $z0$ commands. Furthermore, the algorithm that we are about to describe does not pretend to give an optimum reduction in the length of the DVI code; after all, speed is more important than compactness. But the method is surprisingly effective, and it takes comparatively little time.

We can best understand the basic idea by first considering a simpler problem that has the same essential characteristics. Given a sequence of digits, say $3\,1\,4\,1\,5\,9\,2\,6\,5\,3\,5\,8\,9$, we want to assign subscripts d, y, or z to each digit so as to maximize the number of "y-hits" and "z-hits"; a y-hit is an instance of two appearances of the same digit with the subscript y, where no y's intervene between the two appearances, and a z-hit is defined similarly. For example, the sequence above could be decorated with subscripts as follows:

$$3_z\,1_y\,4_d\,1_y\,5_y\,9_d\,2_d\,6_d\,5_y\,3_z\,5_y\,8_d\,9_d.$$

There are three y-hits ($1_y\ldots1_y$ and $5_y\ldots5_y\ldots5_y$) and one z-hit ($3_z\ldots3_z$); there are no d-hits, since the two appearances of 9_d have d's between them, but we don't count d-hits so it doesn't matter how many there are. These subscripts are analogous to the DVI commands called $down$, y, and z, and the digits are analogous to different amounts of vertical motion; a y-hit or z-hit corresponds to the opportunity to use the one-byte commands $y0$ or $z0$ in a DVI file.

TeX's method of assigning subscripts works like this: Append a new digit, say δ, to the right of the sequence. Now look back through the sequence until one of the following things happens: (a) You see δ_y or δ_z, and this was the first time you encountered a y or z subscript, respectively. Then assign y or z to the new δ; you have scored a hit. (b) You see δ_d, and no y subscripts have been encountered so far during this search. Then change the previous δ_d to δ_y (this corresponds to changing a command in the output buffer), and assign y to the new δ; it's another hit. (c) You see δ_d, and a y subscript has been seen but not a z. Change the previous δ_d to δ_z and assign z to the new δ. (d) You encounter both y and z subscripts before encountering a suitable δ, or you scan all the way to the front of the sequence. Assign d to the new δ; this assignment may be changed later.

The subscripts $3_z\,1_y\,4_d\ldots$ in the example above were, in fact, produced by this procedure, as the reader can verify. (Go ahead and try it.)

605. In order to implement such an idea, TeX maintains a stack of pointers to the $down$, y, and z commands that have been generated for the current page. And there is a similar stack for $right$, w, and x commands. These stacks are called the down stack and right stack, and their top elements are maintained in the variables $down\_ptr$ and $right\_ptr$.

Each entry in these stacks contains four fields: The $width$ field is the amount of motion down or to the right; the $location$ field is the byte number of the DVI command in question (including the appropriate dvi_offset); the $link$ field points to the next item below this one on the stack; and the $info$ field encodes the options for possible change in the DVI command.

#**define** $movement\_node\_size$ 3   ▷ number of words per entry in the down and right stacks ◁
#**define** $location(A)$ $mem[A+2].i$ ▷ DVI byte number for a movement command ◁

⟨ Global variables 13 ⟩ +≡
  static pointer $down\_ptr$, $right\_ptr$;   ▷ heads of the down and right stacks ◁

606. ⟨ Set initial values of key variables 21 ⟩ +≡
  $down\_ptr \leftarrow null$; $right\_ptr \leftarrow null$;

607.   Here is a subroutine that produces a DVI command for some specified downward or rightward motion. It has two parameters: w is the amount of motion, and o is either *down1* or *right1*. We use the fact that the command codes have convenient arithmetic properties: $y1 - down1 \equiv w1 - right1$ and $z1 - down1 \equiv x1 - right1$.

> **static void** *movement*(**scaled** w, **eight_bits** o)
> { **small_number** *mstate*;   ▷ have we seen a y or z? ◁
>   **pointer** p, q;   ▷ current and top nodes on the stack ◁
>   **int** k;   ▷ index into *dvi_buf*, modulo *dvi_buf_size* ◁
> $q \leftarrow get\_node(movement\_node\_size)$;   ▷ new node for the top of the stack ◁
> $width(q) \leftarrow w$; $location(q) \leftarrow dvi\_offset + dvi\_ptr$;
>   **if** $(o \equiv down1)$ { $link(q) \leftarrow down\_ptr$; $down\_ptr \leftarrow q$;
>   }
>   **else** { $link(q) \leftarrow right\_ptr$; $right\_ptr \leftarrow q$;
>   }
>   ⟨ Look at the other stack entries until deciding what sort of DVI command to generate; **goto** *found* if node p is a "hit" 611 ⟩;
>   ⟨ Generate a *down* or *right* command for w and **return** 610 ⟩;
>   *found*: ⟨ Generate a *y0* or *z0* command in order to reuse a previous appearance of w 609 ⟩;
> }

608.   The *info* fields in the entries of the down stack or the right stack have six possible settings: y_here or z_here mean that the DVI command refers to y or z, respectively (or to w or x, in the case of horizontal motion); yz_OK means that the DVI command is *down* (or *right*) but can be changed to either y or z (or to either w or x); y_OK means that it is *down* and can be changed to y but not z; z_OK is similar; and d_fixed means it must stay *down*.

The four settings yz_OK, y_OK, z_OK, d_fixed would not need to be distinguished from each other if we were simply solving the digit-subscripting problem mentioned above. But in TeX's case there is a complication because of the nested structure of *push* and *pop* commands. Suppose we add parentheses to the digit-subscripting problem, redefining hits so that $\delta_y \ldots \delta_y$ is a hit if all y's between the δ's are enclosed in properly nested parentheses, and if the parenthesis level of the right-hand δ_y is deeper than or equal to that of the left-hand one. Thus, '(' and ')' correspond to '*push*' and '*pop*'. Now if we want to assign a subscript to the final 1 in the sequence

$$2_y \, 7_d \, 1_d \, (\, 8_z \, 2_y \, 8_z \,) \, 1$$

we cannot change the previous 1_d to 1_y, since that would invalidate the $2_y \ldots 2_y$ hit. But we can change it to 1_z, scoring a hit since the intervening 8_z's are enclosed in parentheses.

The program below removes movement nodes that are introduced after a *push*, before it outputs the corresponding *pop*.

#**define** y_here 1   ▷ *info* when the movement entry points to a y command ◁
#**define** z_here 2   ▷ *info* when the movement entry points to a z command ◁
#**define** yz_OK 3   ▷ *info* corresponding to an unconstrained *down* command ◁
#**define** y_OK 4   ▷ *info* corresponding to a *down* that can't become a z ◁
#**define** z_OK 5   ▷ *info* corresponding to a *down* that can't become a y ◁
#**define** d_fixed 6   ▷ *info* corresponding to a *down* that can't change ◁

609.   When the *movement* procedure gets to the label *found*, the value of *info*(*p*) will be either *y_here* or *z_here*. If it is, say, *y_here*, the procedure generates a *y0* command (or a *w0* command), and marks all *info* fields between *q* and *p* so that *y* is not OK in that range.

⟨ Generate a *y0* or *z0* command in order to reuse a previous appearance of *w* 609 ⟩ ≡
    info(*q*) ← *info*(*p*);
    if (*info*(*q*) ≡ *y_here*) { *dvi_out*(*o* + *y0* − *down1*);   ▷ *y0* or *w0* ◁
        while (*link*(*q*) ≠ *p*) { *q* ← *link*(*q*);
            switch (*info*(*q*)) {
            case *yz_OK*: *info*(*q*) ← *z_OK*; **break**;
            case *y_OK*: *info*(*q*) ← *d_fixed*; **break**;
            default: *do_nothing*;
            }
        }
    }
    else { *dvi_out*(*o* + *z0* − *down1*);   ▷ *z0* or *x0* ◁
        while (*link*(*q*) ≠ *p*) { *q* ← *link*(*q*);
            switch (*info*(*q*)) {
            case *yz_OK*: *info*(*q*) ← *y_OK*; **break**;
            case *z_OK*: *info*(*q*) ← *d_fixed*; **break**;
            default: *do_nothing*;
            }
        }
    }

This code is used in section 607.

610.   ⟨ Generate a *down* or *right* command for *w* and **return** 610 ⟩ ≡
    info(*q*) ← *yz_OK*;

      $p \leftarrow right\_ptr$; $right\_ptr \leftarrow link(p)$; $free\_node(p, movement\_node\_size)$;
    }
  }

616. The actual distances by which we want to move might be computed as the sum of several separate movements. For example, there might be several glue nodes in succession, or we might want to move right by the width of some box plus some amount of glue. More importantly, the baselineskip distances are computed in terms of glue together with the depth and height of adjacent boxes, and we want the DVI file to lump these three quantities together into a single motion.

   Therefore, TeX maintains two pairs of global variables: dvi_h and dvi_v are the h and v coordinates corresponding to the commands actually output to the DVI file, while cur_h and cur_v are the coordinates corresponding to the current state of the output routines. Coordinate changes will accumulate in cur_h and cur_v without being reflected in the output, until such a change becomes necessary or desirable; we can call the *movement* procedure whenever we want to make $dvi\_h \equiv cur\_h$ or $dvi\_v \equiv cur\_v$.

   The current font reflected in the DVI output is called dvi_f; there is no need for a 'cur_f' variable.

   The depth of nesting of *hlist_out* and *vlist_out* is called cur_s; this is essentially the depth of *push* commands in the DVI output.

#**define** *synch_h*
        if $(cur\_h \neq dvi\_h)$ { $movement(cur\_h - dvi\_h, right1)$; $dvi\_h \leftarrow cur\_h$;
        }
#**define** *synch_v*
        if $(cur\_v \neq dvi\_v)$ { $movement(cur\_v - dvi\_v, down1)$; $dvi\_v \leftarrow cur\_v$;
        }
⟨Global variables 13⟩ +≡

      ⟨Output a leader box at *cur_h*, then advance *cur_h* by *leader_wd* + *lx* 628⟩;
      cur_h ← *edge* − 10; **goto** *next_p*;
    }
  }

This code is used in section 625.

627.   The calculations related to leaders require a bit of care. First, in the case of *a_leaders* (aligned leaders), we want to move *cur_h* to *left_edge* plus the smallest multiple of *leader_wd* for which the result is not less than the current value of *cur_h*; i.e., *cur_h* should become $left\_edge + leader\_wd \times \lceil (cur\_h - left\_edge)/leader\_wd \rceil$. The program here should work in all cases even though some implementations of Pascal give nonstandard results for the / operation when *cur_h* is less than *left_edge*.

In the case of *c_leaders* (centered leaders), we want to increase *cur_h* by half of the excess space not occupied by the leaders; and in the case of *x_leaders* (expanded leaders) we increase *cur_h* by $1/(q+1)$ of this excess space, where q is the number of times the leader box will be replicated. Slight inaccuracies in the division might accumulate; half of this rounding error is placed at each end of the leaders.

⟨ Let *cur_h* be the position of the first box, and set *leader_wd* + *lx* to the spacing between corresponding parts of boxes 627 ⟩ ≡

  if $(subtype(p) \equiv a\_leaders)$ { $save\_h \leftarrow cur\_h$;
    $cur\_h \leftarrow left\_edge + leader\_wd * ((cur\_h - left\_edge)/leader\_wd)$;
    if $(cur\_h < save\_h)$ $cur\_h \leftarrow cur\_h + leader\_wd$;
  }
  else { $lq \leftarrow rule\_wd/leader\_wd$;   ▷ the number of box copies ◁
    $lr \leftarrow rule\_wd \% leader\_wd$;   ▷ the remaining space ◁
    if $(subtype(p) \equiv c\_leaders)$ $cur\_h \leftarrow cur\_h + (lr/2)$;
    else { $lx \leftarrow lr/(lq + 1)$; $cur\_h \leftarrow cur\_h + ((lr - (lq - 1) * lx)/2)$;
    }
  }

This code is used in section 626.

628.   The '*synch*' operations here are intended to decrease the number of bytes needed to specify horizontal and vertical motion in the DVI output.

⟨ Output a leader box at *cur_h*, then advance *cur_h* by *leader_wd* + *lx* 628 ⟩ ≡

  { $cur\_v \leftarrow base\_line + shift\_amount(leader\_box)$; $synch\_v$; $save\_v \leftarrow dvi\_v$;

This code is used in section 642.

644. Packaging.   We're essentially done with the parts of TEX that are concerned with the input (*get_next*) and the output (*ship_out*). So it's time to get heavily into the remaining part, which does the real work of typesetting.

After lists are constructed, TEX wraps them up and puts them into boxes. Two major subroutines are given the responsibility for this task: *hpack* applies to horizontal lists (hlists) and *vpack* applies to vertical lists (vlists). The main duty of *hpack* and *vpack* is to compute the dimensions of the resulting boxes, and to adjust the glue if one of those dimensions is pre-specified. The computed sizes normally enclose all of the material inside the new box; but some items may stick out if negative glue is used, if the box is overfull, or if a \vbox includes other boxes that have been shifted left.

The subroutine call $hpack(p, w, m)$ returns a pointer to an *hlist_node* for a box containing the hlist that starts at p. Parameter w specifies a width; and parameter m is either 'exactly' or 'additional'. Thus, $hpack(p, w, exactly)$ produces a box whose width is exactly w, while $hpack(p, w, additional)$ yields a box whose width is the natural width plus w. It is convenient to define a macro called 'natural' to cover the most common case, so that we can say $hpack(p, natural)$ to get a box that has the natural width of list p.

Similarly, $vpack(p, w, m)$ returns a pointer to a *vlist_node* for a box containing the vlist that starts at p. In this case w represents a height instead of a width; the parameter m is interpreted as in *hpack*.

#**define** *exactly* 0   ▷ a box dimension is pre-specified ◁
#**define** *additional* 1   ▷ a box dimension is increased from the natural one ◁
#**define** *natural* 0, 0, 0, *additional*   ▷ shorthand for parameters to *hpack* and *vpack* ◁

645.   The parameters to *hpack* and *vpack* correspond to TEX's primitives like '\hbox to 300pt', '\hbox spread 10pt'; note that '\hbox' with no dimension following it is equivalent to '\hbox spread 0pt'. The *scan_spec* subroutine scans such constructions in the user's input, including the mandatory left brace that follows them, and it puts the specification onto *save_stack* so that the desired box can later be obtained by executing the following code:

$$save\_ptr \leftarrow save\_ptr - 2;$$
$$hpack(p, saved(1), saved(0)) \ .$$

Special care is necessary to ensure that the special *save_stack* codes are placed just below the new group code, because scanning can change *save_stack* when \csname appears.

   static void *scan_spec*(**group_code** c, **bool** *three_codes*)   ▷ scans a box specification and left brace ◁
  { **int** s;   ▷ temporarily saved value ◁
    int *spec_code*;
    if (*three_codes*) $s \leftarrow saved(0)$;
    if (*scan_keyword*("to")) *spec_code* $\leftarrow$ *exactly*;
    else if (*scan_keyword*("spread")) *spec_code* $\leftarrow$ *additional*;
    else { *spec_code* $\leftarrow$ *additional*; *cur_val* $\leftarrow$ *cur_hfactor* $\leftarrow$ *cur_vfactor* $\leftarrow$ 0; **goto** *found*;
    }
    scan_normal_dimen;
  found:
    if (*three_codes*) { *saved*(0) $\leftarrow$ s; *incr*(*save_ptr*);
    }
    saved(0) $\leftarrow$ *spec_code*; *saved*(1) $\leftarrow$ *cur_val*; *saved_hfactor*(1) $\leftarrow$ *cur_hfactor*;
    saved_vfactor(1) $\leftarrow$ *cur_vfactor*; *save_ptr* $\leftarrow$ *save_ptr* + 2; *new_save_level*(c); *scan_left_brace*( );
  }

646.   To figure out the glue setting, *hpack* and *vpack* determine how much stretchability and shrinkability are present, considering all four orders of infinity. The highest order of infinity that has a nonzero coefficient is then used as if no other orders were present.

For example, suppose that the given list contains six glue nodes with the respective stretchabilities 3pt, 8fill, 5fil, 6pt, −3fil, −8fill. Then the total is essentially 2fil; and if a total additional space of 6pt is to be achieved by stretching, the actual amounts of stretch will be 0pt, 0pt, 15pt, 0pt, −9pt, and 0pt, since only 'fil' glue will be considered. (The 'fill' glue is therefore not really stretching infinitely with respect to 'fil'; nobody would actually want that to happen.)

The arrays *total_stretch* and *total_shrink* are used to determine how much glue of each kind is present. A global variable *last_badness* is used to implement \badness.

⟨ Global variables 13 ⟩ +≡
    static scaled *total_stretch0* [*filll* − *normal* + 1], ∗**const** *total_stretch* ← *total_stretch0* − *normal* ,
        total_shrink0 [*filll* − *normal* + 1], ∗**const** *total_shrink* ← *total_shrink0* − *normal* ;
      ▷ glue found by *hpack* or *vpack* ◁
    static int *last_badness* ;   ▷ badness of the most recently packaged box ◁

647.   If the global variable *adjust_tail* is non-null, the *hpack* routine also removes all occurrences of *ins_node*, *mark_node*, and *adjust_node* items and appends the resulting material onto the list that ends at location *adjust_tail* .

⟨ Global variables 13 ⟩ +≡
    static pointer *adjust_tail* ;   ▷ tail of adjustment list ◁

648.   ⟨ Set initial values of key variables 21 ⟩ +≡
    adjust_tail ← *null* ; *last_badness* ← 0;

649.   Here now is *hpack*, which contains few if any surprises.
    static pointer *hpack* (**pointer** *p*, **scaled** *w*, **scaled** *hf* , **scaled** *vf* , **small_number** *m*);

650.   ⟨ Clear dimensions to zero 650 ⟩ ≡

      default: *do_nothing*;
      }
      $p \leftarrow link(p)$;
    }
  }

652. ⟨Make node p look like a *char_node* and **goto** *reswitch* 652⟩ ≡
  { *mem*[*lig_trick*] $\leftarrow$ *mem*[*lig_char*(p)]; *link*(*lig_trick*) $\leftarrow$ *link*(p); $p \leftarrow$ *lig_trick*; **goto** *reswitch*;
  }

This code is used in sections 622, 651, 1147, and 1726.

653. The code here implicitly uses the fact that running dimensions are indicated by *null_flag*, which will
be ignored in the calculations because it is a highly negative number.

⟨Incorporate box dimensions into the dimensions of the hbox that will contain it 653⟩ ≡
  { $x \leftarrow x + width(p)$;
    if (*type*(p) $\geq$ *rule_node*) $s \leftarrow 0$; **else** $s \leftarrow shift\_amount(p)$;
    if (*height*(p) $- s > h$) $h \leftarrow height(p) - s$;
    if (*depth*(p) $+ s > d$) $d \leftarrow depth(p) + s$;
  }

This code is used in sections 651, 1726, and 1727.

654. The following code is part of TEX's inner loop; i.e., adding another character of text to the user's
input will cause each of these instructions to be exercised one more time.

⟨Incorporate character dimensions into the dimensions of the hbox that will contain it, then move to the
      next node 654⟩ ≡
  { $f \leftarrow font(p)$; $i \leftarrow char\_info(f, character(p))$; $hd \leftarrow height\_depth(i)$; $x \leftarrow x + char\_width(f, i)$;
    $s \leftarrow char\_height(f, hd)$; **if** ($s > h$) $h \leftarrow s$;
    $s \leftarrow char\_depth(f, hd)$; **if** ($s > d$) $d \leftarrow s$;
    $p \leftarrow link(p)$;
  }

This code is used in sections 651 and 1726.

655.   Although node q is not necessarily the immediate predecessor of node p, it always points to some node in the list preceding p. Thus, we can delete nodes by moving q when necessary. The algorithm takes linear time, and the extra computation does not intrude on the inner loop unless it is necessary to make a deletion.

⟨ Transfer node p to the adjustment list 655 ⟩ ≡
  { **while** ($link(q) \neq p$) $q \leftarrow link(q)$;
    if ($type(p) \equiv adjust\_node$) { $link(adjust\_tail) \leftarrow adjust\_ptr(p)$;
      while ($link(adjust\_tail) \neq null$) $adjust\_tail \leftarrow link(adjust\_tail)$;
      $p \leftarrow link(p)$; $free\_node(link(q), small\_node\_size)$;
    }
    else { $link(adjust\_tail) \leftarrow p$; $adjust\_tail \leftarrow p$; $p \leftarrow link(p)$;
    }
    $link(q) \leftarrow p$; $p \leftarrow q$;
  }

This code is used in sections 651 and 1726.

656.   ⟨ Incorporate glue into the horizontal totals 656 ⟩ ≡
  { $g \leftarrow glue\_ptr(p)$; $x \leftarrow x + width(g)$;
    $o \leftarrow stretch\_order(g)$; $total\_stretch[o] \leftarrow total\_stretch[o] + stretch(g)$; $o \leftarrow shrink\_order(g)$;
    $total\_shrink[o] \leftarrow total\_shrink[o] + shrink(g)$;
    if ($subtype(p) \geq a\_leaders$) { $g \leftarrow leader\_ptr(p)$;
      if ($height(g) > h$) $h \leftarrow height(g)$;
      if ($depth(g) > d$) $d \leftarrow depth(g)$;
    }
  }

This code is used in sections 651 and 1726.

657.   When we get to the present part of the program, x is the natural width of the box being packaged.

⟨ Determine the value of $width(r)$ and the appropriate glue setting; then **return** or **goto**

  else prev_depth ← unknown_depth;
}
```

680. Data structures for math mode.   When TeX reads a formula that is enclosed between `$`'s, it constructs an *mlist*, which is essentially a tree structure representing that formula. An mlist is a linear sequence of items, but we can regard it as a tree structure because mlists can appear within mlists. For example, many of the entries can be subscripted or superscripted, and such "scripts" are mlists in their own right.

An entire formula is parsed into such a tree before any of the actual typesetting is done, because the current style of type is usually not known until the formula has been fully scanned. For example, when the formula '`$a+b \over c+d$`' is being read, there is no way to tell that '`a+b`' will be in script size until '`\over`' has appeared.

During the scanning process, each element of the mlist being built is classified as a relation, a binary operator, an open parenthesis, etc., or as a construct like '`\sqrt`' that must be built up. This classification appears in the mlist data structure.

After a formula has been fully scanned, the mlist is converted to an hlist so that it can be incorporated into the surrounding text. This conversion is controlled by a recursive procedure that decides all of the appropriate styles by a "top-down" process starting at the outermost level and working in towards the subformulas. The formula is ultimately pasted together using combinations of horizontal and vertical boxes, with glue and penalty nodes inserted as necessary.

An mlist is represented internally as a linked list consisting chiefly of "noads" (pronounced "no-adds"), to distinguish them from the somewhat similar "nodes" in hlists and vlists. Certain kinds of ordinary nodes are allowed to appear in mlists together with the noads; TeX tells the difference by means of the *type* field, since a noad's *type* is always greater than that of a node. An mlist does not contain character nodes, hlist nodes, vlist nodes, math nodes, ligature nodes, or unset nodes; in particular, each mlist item appears in the variable-size part of *mem*, so the *type* field is always present.

681.   Each noad is four or more words long. The first word contains the *type* and *subtype* and *link* fields that are already so familiar to us; the second, third, and fourth words are called the noad's *nucleus*, *subscr*, and *supscr* fields.

Consider, for example, the simple formula 'x^2', which would be parsed into an mlist containing a single element called an *ord_noad*. The *nucleus* of this noad is a representation of 'x', the *subscr* is empty, and the *supscr* is a representation of '2'.

The *nucleus*, *subscr*, and *supscr* fields are further broken into subfields. If p points to a noad, and if q is one of its principal fields (e.g., $q \equiv subscr(p)$), there are several possibilities for the subfields, depending on the *math_type* of q.

$math\_type(q) \equiv math\_char$ means that $fam(q)$ refers to one of the sixteen font families, and $character(q)$ is the number of a character within a font of that family, as in a character node.

$math\_type(q) \equiv math\_text\_char$ is similar, but the character is unsubscripted and unsuperscripted and it is followed immediately by another character from the same font. (This *math_type* setting appears only briefly during the processing; it is used to suppress unwanted italic corrections.)

$math\_type(q) \equiv empty$ indicates a field with no value (the corresponding attribute of noad p is not present).

$math\_type(q) \equiv sub\_box$ means that $info(q)$ points to a box node (either an *hlist_node* or a *vlist_node*) that should be used as the value of the field. The *shift_amount* in the subsidiary box node is the amount by which that box will be shifted downward.

$math\_type(q) \equiv sub\_mlist$ means that $info(q)$ points to an mlist; the mlist must be converted to an hlist in order to obtain the value of this field.

In the latter case, we might have $info(q) \equiv null$. This is not the same as $math\_type(q) \equiv empty$; for example, '$P\_\{\}$' and '$P$' produce different results (the former will not have the "italic correction" added to the width of P, but the "script skip" will be added).

The definitions of subfields given here are evidently wasteful of space, since a halfword is being used for the *math_type* although only three bits would be needed. However, there are hardly ever many noads present at once, since they are soon converted to nodes that take up even more space, so we can afford to represent them in whatever way simplifies the programming.

#**define** *noad_size* 4   ▷ number of words in a normal noad ◁
#**define** *nucleus*(A) $A + 1$ ▷ the *nucleus* field of a noad ◁
#**define** *supscr*(A) $A + 2$ ▷ the *supscr* field of a noad ◁
#**define** *subscr*(A) $A + 3$ ▷ the *subscr* field of a noad ◁

#**define** *math_char* 1   ▷ *math_type* when the attribute is simple ◁
#**define** *sub_box* 2   ▷ *math_type* when the attribute is a box ◁
#**define** *sub_mlist* 3   ▷ *math_type* when the attribute is a formula ◁
#**define** *math_text_char* 4   ▷ *math_type* when italic correction is dubious ◁

682.   Each portion of a formula is classified as Ord, Op, Bin, Rel, Open, Close, Punct, or Inner, for purposes of spacing and line breaking. An *ord_noad*, *op_noad*, *bin_noad*, *rel_noad*, *open_noad*, *close_noad*, *punct_noad*, or *inner_noad* is used to represent portions of the various types. For example, an '=' sign in a formula leads to the creation of a *rel_noad* whose *nucleus* field is a representation of an equals sign (usually $fam \equiv 0$, $character \equiv °75$). A formula preceded by \mathrel also results in a *rel_noad*. When a *rel_noad* is followed by an *op_noad*, say, and possibly separated by one or more ordinary nodes (not noads), TeX will insert a penalty node (with the current *rel_penalty*) just after the formula that corresponds to the *rel_noad*, unless there already was a penalty immediately following; and a "thick space" will be inserted just before the formula that corresponds to the *op_noad*.

A noad of type *ord_noad*, *op_noad*, ..., *inner_noad* usually has a $subtype \equiv normal$. The only exception is that an *op_noad* might have $subtype \equiv limits$ or *no_limits*, if the normal positioning of limits has been overridden for this operator.

#**define** *ord_noad*   ($unset\_node + 3$)   ▷ *type* of a noad classified Ord ◁
#**define** *op_noad*   ($ord\_noad + 1$)   ▷ *type* of a noad classified Op ◁
#**define** *bin_noad*   ($ord\_noad + 2$)   ▷ *type* of a noad classified Bin ◁

#**define** *inner_noad*   ($ord\_noad + 7$)   ▷ *type* of a noad classified Inner ◁
#**define** *limits*   1   ▷ *subtype* of *op_noad* whose scripts are to be above, below ◁
#**define** *no_limits*   2   ▷ *subtype* of *op_noad* whose scripts are to be normal ◁

683.   A *radical_noad* is five words long; the fifth word is the *left_delimiter* field, which usually represents a square root sign.

A *fraction_noad* is six words long; it has a *right_delimiter* field as well as a *left_delimiter*.

Delimiter fields are of type **four_quarters**, and they have four subfields called *small_fam*, *small_char*, *large_fam*, *large_char*. These subfields represent variable-size delimiters by giving the "small" and "large" starting characters, as explained in Chapter 17 of *The TeXbook*.

A *fraction_noad* is actually quite different from all other noads. Not only does it have six words, it has *thickness*, *denominator*, and *numerator* fields instead of *nucleus*, *subscr*, and *supscr*. The *thickness* is a scaled value that tells how thick to make a fraction rule; however, the special value *default_code* is used to stand for the *default_rule_thickness* of the current size. The *numerator* and *denominator* point to mlists that define a fraction; we always have

$$math\_type(numerator) \equiv math\_type(denominator) \equiv sub\_mlist.$$

The *left_delimiter* and *right_delimiter* fields specify delimiters that will be placed at the left and right of the fraction. In this way, a *fraction_noad* is able to represent all of TeX's operators \over, \atop, \above, \overwithdelims, \atopwithdelims, and \abovewithdelims.

#**define** *left_delimiter*(A) A + 4   ▷ first delimiter field of a noad ◁
#**define** *right_delimiter*(A) A + 5   ▷ second delimiter field of a fraction noad ◁
#**define** *radical_noad* (*inner_noad* + 1)   ▷ *type* of a noad for square roots ◁
#**define** *radical_noad_size* 5   ▷ number of *mem* words in a radical noad ◁
#**define** *fraction_noad* (*radical_noad* + 1)   ▷ *type* of a noad for generalized fractions ◁
#**define** *fraction_noad_size* 6   ▷ number of *mem* words in a fraction noad ◁
#**define** *small_fam*(A) mem[A].qqqq.b0   ▷ *fam* for "small" delimiter ◁
#**define** *small_char*(A) mem[A].qqqq.b1   ▷ *character* for "small" delimiter ◁
#**define** *large_fam*(A) mem[A].qqqq.b2   ▷ *fam* for "large" delimiter ◁
#**define** *large_char*(A) mem[A].qqqq.b3   ▷ *character* for "large" delimiter ◁
#**define** *thickness*(A) *width*(A)   ▷ *thickness* field in a fraction noad ◁
#**define** *default_code* °10000000000   ▷ denotes *default_rule_thickness* ◁
#**define** *numerator*(A) *supscr*(A)   ▷ *numerator* field in a fraction noad ◁
#**define** *denominator*(A) *subscr*(A)   ▷ *denominator* field in a fraction noad ◁

684.   The global variable *empty_field* is set up for initialization of empty fields in new noads. Similarly, *null_delimiter* is for the initialization of delimiter fields.

⟨ Global variables 13 ⟩ +≡
  static two_halves *empty_field*;
  static four_quarters *null_delimiter*;

685.   ⟨ Set initial values of key variables 21 ⟩ +≡
  empty_field.rh ← *empty*; *empty_field*.lh ← *null*;
  null_delimiter.b0 ← 0; *null_delimiter*.b1 ← *min_quarterword*;
  null_delimiter.b2 ← 0; *null_delimiter*.b3 ← *min_quarterword*;

686.   The *new_noad* function creates an *ord_noad* that is completely null.

  static pointer *new_noad*(**void**)
  { **pointer** *p*;

    p ← *get_node*(*noad_size*); *type*(*p*) ← *ord_noad*; *subtype*(*p*) ← *normal*;
    mem[*nucleus*(*p*)].hh ← *empty_field*; mem[*subscr*(*p*)].hh ← *empty_field*;
    mem[*supscr*(*p*)].hh ← *empty_field*; **return** *p*;
  }

687. A few more kinds of noads will complete the set: An *under_noad* has its nucleus underlined; an *over_noad* has it overlined. An *accent_noad* places an accent over its nucleus; the accent character appears as *fam*(*accent_chr*(*p*)) and *character*(*accent_chr*(*p*)). A *vcenter_noad* centers its nucleus vertically with respect to the axis of the formula; in such noads we always have *math_type*(*nucleus*(*p*)) ≡ *sub_box*.

And finally, we have *left_noad* and *right_noad* types, to implement TEX's \left and \right as well as ε-TEX's \middle. The *nucleus* of such noads is replaced by a *delimiter* field; thus, for example, '\left(' produces a *left_noad* such that *delimiter*(*p*) holds the family and character codes for all left parentheses. A *left_noad* never appears in an mlist except as the first element, and a *right_noad* never appears in an mlist except as the last element; furthermore, we either have both a *left_noad* and a *right_noad*, or neither one is present. The *subscr* and *supscr* fields are always *empty* in a *left_noad* and a *right_noad*.

#**define** *under_noad* (*fraction_noad* + 1)   ▷ *type* of a noad for underlining ◁
#**define** *over_noad* (*under_noad* + 1)   ▷ *type* of a noad for overlining ◁
#**define** *accent_noad* (*over_noad* + 1)   ▷ *type* of a noad for accented subformulas ◁
#**define** *accent_noad_size* 5   ▷ number of *mem* words in an accent noad ◁
#**define** *accent_chr*(*A*) *A* + 4   ▷ the *accent_chr* field of an accent noad ◁
#**define** *vcenter_noad* (*accent_noad* + 1)   ▷ *type* of a noad for \vcenter ◁
#**define** *left_noad* (*vcenter_noad* + 1)   ▷ *type* of a noad for \left ◁
#**define** *right_noad* (*left_noad* + 1)   ▷ *type* of a noad for \right ◁
#**define** *delimiter*(*A*) *nucleus*(*A*)   ▷ *delimiter* field in left and right noads ◁
#**define** *middle_noad* 1   ▷ *subtype* of right noad representing \middle ◁
#**define** *scripts_allowed*(*A*) (*type*(*A*) ≥ *ord_noad*) ∧ (*type*(*A*) < *left_noad*)

688. Math formulas can also contain instructions like \textstyle that override TEX's normal style rules. A *style_node* is inserted into the data structure to record such instructions; it is three words long, so it is considered a node instead of a noad. The *subtype* is either *display_style* or *text_style* or *script_style* or *script_script_style*. The second and third words of a *style_node* are not used, but they are present because a *choice_node* is converted to a *style_node*.

TEX uses even numbers 0, 2, 4, 6 to encode the basic styles *display_style*, ..., *script_script_style*, and adds 1 to get the "cramped" versions of these styles. This gives a numerical order that is backwards from the convention of Appendix G in *The TEXbook*; i.e., a smaller style has a larger numerical value.

#**define** *style_node* (*unset_node* + 1)   ▷ *type* of a style node ◁
#**define** *style_node_size* 3   ▷ number of words in a style node ◁
#**define** *display_style* 0   ▷ *subtype* for \displaystyle ◁
#**define** *text_style* 2   ▷ *subtype* for \textstyle ◁
#**define** *script_style* 4   ▷ *subtype* for \scriptstyle ◁
#**define** *script_script_style* 6   ▷ *subtype* for \scriptscriptstyle ◁
#**define** *cramped* 1   ▷ add this to an uncramped style if you want to cramp it ◁

  static pointer *new_style*(**small_number** *s*)   ▷ create a style node ◁
  { **pointer** *p*;   ▷ the new node ◁

    p ← *get_node*(*style_node_size*); *type*(*p*) ← *style_node*; *subtype*(*p*) ← *s*; *width*(*p*) ← 0; *depth*(*p*) ← 0;
      ▷ the *width* and *depth* are not used ◁
    return *p*;
  }

689.   Finally, the \mathchoice primitive creates a *choice_node*, which has special subfields *display_mlist*, *text_mlist*, *script_mlist*, and *script_script_mlist* pointing to the mlists for each style.

#**define** *choice_node* (*unset_node* + 2)   ▷ *type* of a choice node ◁
#**define** *display_mlist*(A) *info*(A + 1)   ▷ mlist to be used in display style ◁
#**define** *text_mlist*(A) *link*(A + 1)   ▷ mlist to be used in text style ◁
#**define** *script_mlist*(A) *info*(A + 2)   ▷ mlist to be used in script style ◁
#**define** *script_script_mlist*(A) *link*(A + 2)   ▷ mlist to be used in scriptscript style ◁

   static pointer *new_choice*(**void**)   ▷ create a choice node ◁
   { **pointer** p;   ▷ the new node ◁

     $p \leftarrow get\_node(style\_node\_size)$; $type(p) \leftarrow choice\_node$; $subtype(p) \leftarrow 0$;   ▷ the *subtype* is not used ◁
     $display\_mlist(p) \leftarrow null$; $text\_mlist(p) \leftarrow null$; $script\_mlist(p) \leftarrow null$;
     $script\_script\_mlist(p) \leftarrow null$; **return** p;
   }

690.   Let's consider now the previously unwritten part of *show_node_list* that displays the things that can only be present in mlists; this program illustrates how to access the data structures just defined.

In the context of the following program, p points to a node or noad that should be displayed, and the current string contains the "recursion history" that leads to this point. The recursion history consists of a dot for each outer level in which p is subsidiary to some node, or in which p is subsidiary to the *nucleus* field of some noad; the dot is replaced by '_' or '^' or '/' or '\' if p is descended from the *subscr* or *supscr* or *denominator* or *numerator* fields of noads. For example, the current string would be '.^._/' if p points to the *ord_noad* for x in the (ridiculous) formula '$\sqrt{a^{\mathinner{b_{c\over x+y}}}}$'.

⟨ Cases of *show_node_list* that arise in mlists only 690 ⟩ ≡
case *style_node*: *print_style*(*subtype*(p)); **break**;
case *choice_node*: ⟨ Display choice node p 695 ⟩ **break**;

This code is used in section 183.

691.   Here are some simple routines used in the display of noads.

⟨ Declare procedures needed for displaying the elements of mlists 691 ⟩ ≡
  static void *print_fam_and_char*(**pointer** p)   ▷ prints family and character ◁
  { *print_esc*("fam"); *print_int*(*fam*(p)); *print_char*('␣'); *print_ASCII*(*qo*(*character*(p)));
  }
  static void *print_delimiter*(**pointer** p)   ▷ prints a delimiter as 24-bit hex value ◁
  { **int** a;   ▷ accumulator ◁

    $a \leftarrow small\_fam(p) * 256 + qo(small\_char(p))$; $a \leftarrow a * {}^{\#}1000 + large\_fam(p) * 256 + qo(large\_char(p))$;
    if $(a < 0)$ *print_int*(a);   ▷ this should never happen ◁
    else *print_hex*(a);
  }
See also sections 692 and 694.
This code is used in section 179.

692.   The next subroutine will descend to another level of recursion when a subsidiary mlist needs to be displayed. The parameter c indicates what character is to become part of the recursion history. An empty mlist is distinguished from a field with $math\_type(p) \equiv empty$, because these are not equivalent (as explained above).

⟨ Declare procedures needed for displaying the elements of mlists 691 ⟩ +≡
  static void $show\_info(\mathbf{void})$;   ▷ $show\_node\_list(info(temp\_ptr))$ ◁

  static void $print\_subsidiary\_data(\mathbf{pointer}\ p, \mathbf{ASCII\_code}\ c)$ ▷ display a noad field ◁
  { **if** $(cur\_length \geq depth\_threshold)$ { **if** $(math\_type(p) \neq empty)$ $print("\_[]")$;
    }
   else { $append\_char(c)$;   ▷ include c in the recursion history ◁
     $temp\_ptr \leftarrow p$;   ▷ prepare for $show\_info$ if recursion is needed ◁
     switch $(math\_type(p))$ {
     case $math\_char$:
      { $print\_ln()$; $print\_current\_string()$; $print\_fam\_and\_char(p)$;
      } **break**;
     case sub_box: $show\_info()$; **break**;   ▷ recursive call ◁
     case sub_mlist:
      if $(info(p) \equiv null)$ { $print\_ln()$; $print\_current\_string()$; $print("\{\}")$;
      }
      else $show\_info()$; **break**;   ▷ recursive call ◁
     default: $do\_nothing$;   ▷ empty ◁
     }
     $flush\_char$;   ▷ remove c from the recursion history ◁
    }
  }

693.   The inelegant introduction of $show\_info$ in the code above seems better than the alternative of using Pascal's strange *forward* declaration for a procedure with parameters. The Pascal convention about dropping parameters from a post-*forward* procedure is, frankly, so intolerable to the author of TeX that he would rather stoop to communication via a global temporary variable. (A similar stoopidity occurred with respect to $hlist\_out$ and $vlist\_out$ above, and it will occur with respect to $mlist\_to\_hlist$ below.)

  static void $show\_info(\mathbf{void})$ ▷ the reader will kindly forgive this ◁
  { $show\_node\_list(info(temp\_ptr))$;
  }

694.   ⟨ Declare procedures needed for displaying the elements of mlists 691 ⟩ +≡
  static void $print\_style(\mathbf{int}\ c)$
  { **switch** $(c/2)$ {
   case 0: $print\_esc("displaystyle")$; **break**;   ▷ $display\_style \equiv 0$ ◁
   case 1: $print\_esc("textstyle")$; **break**;   ▷ $text\_style \equiv 2$ ◁
   case 2: $print\_esc("scriptstyle")$; **break**;   ▷ $script\_style \equiv 4$ ◁
   case 3: $print\_esc("scriptscriptstyle")$; **break**;   ▷ $script\_script\_style \equiv 6$ ◁
   default: $print("Unknown\_style!")$;
   }
  }

695. ⟨Display choice node p 695⟩ ≡
{ $print\_esc$("mathchoice"); $append\_char$('D'); $show\_node\_list$($display\_mlist$(p)); $flush\_char$;
  $append\_char$('T'); $show\_node\_list$($text\_mlist$(p)); $flush\_char$; $append\_char$('S');
  $show\_node\_list$($script\_mlist$(p)); $flush\_char$; $append\_char$('s');
  $show\_node\_list$($script\_script\_mlist$(p)); $flush\_char$;
}

This code is used in section 690.

696. ⟨Display normal noad p 696⟩ ≡
{ **switch** ($type$(p)) {
  case ord_noad: $print\_esc$("mathord"); **break**;
  case op_noad: $print\_esc$("mathop"); **break**;
  case bin_noad: $print\_esc$("mathbin"); **break**;
  case rel_noad: $print\_esc$("mathrel"); **break**;

    { $print\_esc$("radical"); $print\_delimiter$($left\_delimiter$(p));
    } **break**;
  case $accent\_noad$:
    { $print\_esc$("accent"); $print\_fam\_and\_char$($accent\_chr$(p));
    } **break**;
  case $left\_noad$:
    { $print\_esc$("left"); $print\_delimiter$($delimiter$(p));
    } **break**;
  case $right\_noad$:
    { **if** ($subtype$(p) ≡ $normal$) $print\_esc$("right");
      else $print\_esc$("middle");
      $print\_delimiter$($delimiter$(p));
    }
  }
  if ($type$(p) < $left\_noad$) { **if** ($subtype$(p) ≠ $normal$)
      if ($subtype$(p) ≡ $limits$) $print\_esc$("limits");
      else $print\_esc$("nolimits");
    $print\_subsidiary\_data$($nucleus$(p), '.');
  }
  $print\_subsidiary\_data$($supscr$(p), '^'); $print\_subsidiary\_data$($subscr$(p), '_');
}

This code is used in section 690.

697.   ⟨Display fraction noad p 697⟩ ≡
{ $print\_esc(\texttt{"fraction,}_{\sqcup}\texttt{thickness}_{\sqcup}\texttt{"})$;
  if $(thickness(p) \equiv default\_code)$ $print(\texttt{"=}_{\sqcup}\texttt{default"})$;
  else $print\_scaled(thickness(p))$;
  if $((small\_fam(left\_delimiter(p)) \neq 0) \lor (small\_char(left\_delimiter(p)) \neq min\_quarterword) \lor$
         $(large\_fam(left\_delimiter(p)) \neq 0) \lor (large\_char(left\_delimiter(p)) \neq min\_quarterword))$ {
    $print(\texttt{",}_{\sqcup}\texttt{left-delimiter}_{\sqcup}\texttt{"})$; $print\_delimiter(left\_delimiter(p))$;
  }
  if $((small\_fam(right\_delimiter(p)) \neq 0) \lor (small\_char(right\_delimiter(p)) \neq min\_quarterword) \lor$
         $(large\_fam(right\_delimiter(p)) \neq 0) \lor (large\_char(right\_delimiter(p)) \neq min\_quarterword))$ {
    $print(\texttt{",}_{\sqcup}\texttt{right-delimiter}_{\sqcup}\texttt{"})$; $print\_delimiter(right\_delimiter(p))$;
  }
  $print\_subsidiary\_data(numerator(p), \texttt{'\textbackslash\textbackslash'})$; $print\_subsidiary\_data(denominator(p), \texttt{'/'})$;
}

This code is used in section 690.

698.   That which can be displayed can also be destroyed.

⟨Cases of $flush\_node\_list$ that arise in mlists only 698⟩ ≡
case $style\_node$:
  { $free\_node(p, style\_node\_size)$; **goto** $done$;
  }
case $choice\_node$:

  { $flush\_node\_list(info(numerator(p)))$; $flush\_node\_list(info(denominator(p)))$;
    $free\_node(p, fraction\_noad\_size)$; **goto** $done$;
  }

This code is used in section 202.

699. Subroutines for math mode.   In order to convert mlists to hlists, i.e., noads to nodes, we need several subroutines that are conveniently dealt with now.

Let us first introduce the macros that make it easy to get at the parameters and other font information. A size code, which is a multiple of 16, is added to a family number to get an index into the table of internal font numbers for each combination of family and size. (Be alert: Size codes get larger as the type gets smaller.)

#**define** $text\_size$ 0   ▷ size code for the largest size in a family ◁
#**define** $script\_size$ 16   ▷ size code for the medium size in a family ◁
#**define** $script\_script\_size$ 32   ▷ size code for the smallest size in a family ◁

⟨ Basic printing procedures 56 ⟩ +≡
  static void $print\_size$(**int** s)
  { **if** ($s \equiv text\_size$) $print\_esc$("textfont");
    else if ($s \equiv script\_size$) $print\_esc$("scriptfont");
    else $print\_esc$("scriptscriptfont");
  }

700.   Before an mlist is converted to an hlist, TeX makes sure that the fonts in family 2 have enough parameters to be math-symbol fonts, and that the fonts in family 3 have enough parameters to be math-extension fonts. The math-symbol parameters are referred to by using the following macros, which take a size code as their parameter; for example, $num1$(cur_size) gives the value of the $num1$ parameter for the current size.

#**define** $mathsy\_end(A)$ $fam\_fnt(2+A)$]] . sc
#**define** $mathsy(A)$ $font\_info$ [$A + param\_base$ [$mathsy\_end$
#**define** $math\_x\_height$ $mathsy(5)$ ▷ height of 'x' ◁
#**define** $math\_quad$ $mathsy(6)$ ▷ 18mu ◁
#**define** $num1$ $mathsy(8)$ ▷ numerator shift-up in display styles ◁
#**define** $num2$ $mathsy(9)$ ▷ numerator shift-up in non-display, non-\atop ◁
#**define** $num3$ $mathsy(10)$ ▷ numerator shift-up in non-display \atop ◁
#**define** $denom1$ $mathsy(11)$ ▷ denominator shift-down in display styles ◁
#**define** $denom2$ $mathsy(12)$ ▷ denominator shift-down in non-display styles ◁
#**define** $sup1$ $mathsy(13)$ ▷ superscript shift-up in uncramped display style ◁
#**define** $sup2$ $mathsy(14)$ ▷ superscript shift-up in uncramped non-display ◁
#**define** $sup3$ $mathsy(15)$ ▷ superscript shift-up in cramped styles ◁
#**define** $sub1$ $mathsy(16)$ ▷ subscript shift-down if superscript is absent ◁
#**define** $sub2$ $mathsy(17)$ ▷ subscript shift-down if superscript is present ◁
#**define** sup_drop $mathsy(18)$ ▷ superscript baseline below top of large box ◁
#**define** sub_drop $mathsy(19)$ ▷ subscript baseline below bottom of large box ◁
#**define** $delim1$ $mathsy(20)$ ▷ size of \atopwithdelims delimiters in display styles ◁
#**define** $delim2$ $mathsy(21)$ ▷ size of \atopwithdelims delimiters in non-displays ◁
#**define** $axis\_height$ $mathsy(22)$ ▷ height of fraction lines above the baseline ◁
#**define** $total\_mathsy\_params$ 22

701.   The math-extension parameters have similar macros, but the size code is omitted (since it is always cur_size when we refer to such parameters).

#**define** $mathex(A)$ $font\_info[A + param\_base[fam\_fnt(3 + cur\_size)]].sc$
#**define** $default\_rule\_thickness$ $mathex(8)$ ▷ thickness of \over bars ◁
#**define** $big\_op\_spacing1$ $mathex(9)$ ▷ minimum clearance above a displayed op ◁
#**define** $big\_op\_spacing2$ $mathex(10)$ ▷ minimum clearance below a displayed op ◁
#**define** $big\_op\_spacing3$ $mathex(11)$ ▷ minimum baselineskip above displayed op ◁
#**define** $big\_op\_spacing4$ $mathex(12)$ ▷ minimum baselineskip below displayed op ◁
#**define** $big\_op\_spacing5$ $mathex(13)$ ▷ padding above and below displayed limits ◁
#**define** $total\_mathex\_params$ 13

702. We also need to compute the change in style between mlists and their subsidiaries. The following macros define the subsidiary style for an overlined nucleus (*cramped_style*), for a subscript or a superscript (*sub_style* or *sup_style*), or for a numerator or denominator (*num_style* or *denom_style*).

#**define** $cramped\_style(A)$ $2 * (A/2) + cramped$ ▷ cramp the style ◁
#**define** $sub\_style(A)$ $2 * (A/4) + script\_style + cramped$ ▷ smaller and cramped ◁
#**define** $sup\_style(A)$ $2 * (A/4) + script\_style + (A \% 2)$ ▷ smaller ◁
#**define** $num\_style(A)$ $A + 2 - 2 * (A/6)$ ▷ smaller unless already script-script ◁
#**define** $denom\_style(A)$ $2 * (A/2) + cramped + 2 - 2 * (A/6)$ ▷ smaller, cramped ◁

703. When the style changes, the following piece of program computes associated information:

⟨ Set up the values of *cur_size* and *cur_mu*, based on *cur_style* 703 ⟩ ≡
  { **if** $(cur\_style < script\_style)$ $cur\_size \leftarrow text\_size$;
    else $cur\_size \leftarrow 16 * ((cur\_style - text\_style)/2)$;
    $cur\_mu \leftarrow x\_over\_n(math\_quad(cur\_size), 18)$;
  }

This code is used in sections 720, 726, 727, 730, 754, 760, 762, and 763.

704. Here is a function that returns a pointer to a rule node having a given thickness t. The rule will extend horizontally to the boundary of the vlist that eventually contains it.

  static pointer $fraction\_rule(\textbf{scaled } t)$ ▷ construct the bar for a fraction ◁
  { **pointer** p;   ▷ the new node ◁
    $p \leftarrow new\_rule(\,)$; $height(p) \leftarrow t$; $depth(p) \leftarrow 0$; **return** p;
  }

705. The *overbar* function returns a pointer to a vlist box that consists of a given box b, above which has been placed a kern of height k under a fraction rule of thickness t under additional space of height t.

  static pointer $overbar(\textbf{pointer } b, \textbf{scaled } k, \textbf{scaled } t)$
  { **pointer** p, q;   ▷ nodes being constructed ◁
    $p \leftarrow new\_kern(k)$; $link(p) \leftarrow b$; $q \leftarrow fraction\_rule(t)$; $link(q) \leftarrow p$; $p \leftarrow new\_kern(t)$; $link(p) \leftarrow q$;
    return $vpack(p, natural)$;
  }

706. The *var_delimiter* function, which finds or constructs a sufficiently large delimiter, is the most interesting of the auxiliary functions that currently concern us. Given a pointer d to a delimiter field in some noad, together with a size code s and a vertical distance v, this function returns a pointer to a box that contains the smallest variant of d whose height plus depth is v or more. (And if no variant is large enough, it returns the largest available variant.) In particular, this routine will construct arbitrarily large delimiters from extensible components, if d leads to such characters.

The value returned is a box whose *shift_amount* has been set so that the box is vertically centered with respect to the axis in the given size. If a built-up symbol is returned, the height of the box before shifting will be the height of its topmost component.

⟨ Declare subprocedures for *var_delimiter* 709 ⟩

   static pointer *var_delimiter*(**pointer** d, **small_number** s, **scaled** v)
   { **pointer** b;   ▷ the box that will be constructed ◁
     internal_font_number f, g;   ▷ best-so-far and tentative font codes ◁
     quarterword c, x, y;   ▷ best-so-far and tentative character codes ◁
     int m, n;   ▷ the number of extensible pieces ◁
     scaled u;   ▷ height-plus-depth of a tentative character ◁
     scaled w;   ▷ largest height-plus-depth so far ◁
     four_quarters q;   ▷ character info ◁
     eight_bits hd;   ▷ height-depth byte ◁
     four_quarters r;   ▷ extensible pieces ◁
     small_number z;   ▷ runs through font family members ◁
     bool *large_attempt*;   ▷ are we trying the "large" variant? ◁

     $f \leftarrow null\_font$; $w \leftarrow 0$; *large_attempt* $\leftarrow false$; $z \leftarrow small\_fam(d)$; $x \leftarrow small\_char(d)$;
     loop { ⟨ Look at the variants of (z, x); set f and c whenever a better character is found; **goto** *found*
           as soon as a large enough variant is encountered 707 ⟩;
       if (*large_attempt*) **goto** *found*;   ▷ there were none large enough ◁
       large_attempt $\leftarrow true$; $z \leftarrow large\_fam(d)$; $x \leftarrow large\_char(d)$;
     }
   found:
     if $(f \neq null\_font)$ ⟨ Make variable b point to a box for (f, c) 710 ⟩;
     else { $b \leftarrow new\_null\_box(\,)$; $width(b) \leftarrow null\_delimiter\_space$;
        ▷ use this width if no delimiter was found ◁
     }
     $shift\_amount(b) \leftarrow half(height(b) - depth(b)) - axis\_height(s)$; **return** b;
   }

707. The search process is complicated slightly by the facts that some of the characters might not be present in some of the fonts, and they might not be probed in increasing order of height.

⟨ Look at the variants of (z, x); set f and c whenever a better character is found; **goto** *found* as soon as a large enough variant is encountered 707 ⟩ ≡
  if $((z \neq 0) \vee (x \neq min\_quarterword))$ { $z \leftarrow z + s + 16$;
    do {
      $z \leftarrow z - 16$; $g \leftarrow fam\_fnt(z)$;
      if $(g \neq null\_font)$ ⟨ Look at the list of characters starting with x in font g; set f and c whenever a
          better character is found; **goto** *found* as soon as a large enough variant is encountered 708 ⟩;
    } **while** $(\neg(z < 16))$;
  }

This code is used in section 706.

708. ⟨Look at the list of characters starting with x in font g; set f and c whenever a better character is found; **goto** *found* as soon as a large enough variant is encountered 708⟩ ≡

```
{ y ← x;
  if ((qo(y) ≥ font_bc[g]) ∧ (qo(y) ≤ font_ec[g])) { resume: q ← char_info(g, y);
    if (char_exists(q)) { if (char_tag(q) ≡ ext_tag) { f ← g;  c ← y;  goto found;
      }
      hd ← height_depth(q);  u ← char_height(g, hd) + char_depth(g, hd);
      if (u > w) { f ← g;  c ← y;  w ← u;
        if (u ≥ v) goto found;
      }
      if (char_tag(q) ≡ list_tag) { y ← rem_byte(q); goto resume;
      }
    }
  }
}
```

This code is used in section 707.

709. Here is a subroutine that creates a new box, whose list contains a single character, and whose width includes the italic correction for that character. The height or depth of the box will be negative, if the height or depth of the character is negative; thus, this routine may deliver a slightly different result than *hpack* would produce.

⟨Declare subprocedures for *var_delimiter* 709⟩ ≡

```
static pointer char_box(internal_font_number f, quarterword c)
{ four_quarters q;
  eight_bits hd;      ▷ height_depth byte ◁
  pointer b, p;       ▷ the new box and its character node ◁

  q ← char_info(f, c);  hd ← height_depth(q);  b ← new_null_box();
  width(b) ← char_width(f, q) + char_italic(f, q);  height(b) ← char_height(f, hd);
  depth(b) ← char_depth(f, hd);  p ← get_avail();  character(p) ← c;  font(p) ← f;  list_ptr(b) ← p;
  return b;
}
```

See also sections 711 and 712.

This code is used in section 706.

710. When the following code is executed, $char\_tag(q)$ will be equal to ext_tag if and only if a built-up symbol is supposed to be returned.

⟨Make variable b point to a box for (f, c) 710⟩ ≡

```
if (char_tag(q) ≡ ext_tag)
  ⟨Construct an extensible character in a new box b, using recipe rem_byte(q) and font f 713⟩
else b ← char_box(f, c)
```

This code is used in section 706.

711. When we build an extensible character, it's handy to have the following subroutine, which puts a given character on top of the characters already in box b:

⟨Declare subprocedures for *var_delimiter* 709⟩ +≡

```
static void stack_into_box(pointer b, internal_font_number f, quarterword c)
{ pointer p;      ▷ new node placed into b ◁

  p ← char_box(f, c);  link(p) ← list_ptr(b);  list_ptr(b) ← p;  height(b) ← height(p);
}
```

712.   Another handy subroutine computes the height plus depth of a given character:

⟨ Declare subprocedures for *var_delimiter* 709 ⟩ +≡
  static scaled *height_plus_depth*(**internal_font_number** f, **quarterword** c)
  { **four_quarters** q;
    eight_bits hd;   ▷ *height_depth* byte ◁
    $q \leftarrow char\_info(f, c)$; $hd \leftarrow height\_depth(q)$; **return** $char\_height(f, hd) + char\_depth(f, hd)$;
  }

713.   ⟨ Construct an extensible character in a new box b, using recipe *rem_byte*(q) and font f 713 ⟩ ≡
  { $b \leftarrow new\_null\_box(\ )$; $type(b) \leftarrow vlist\_node$; $r \leftarrow font\_info[exten\_base[f] + rem\_byte(q)].qqqq$;
    ⟨ Compute the minimum suitable height, w, and the corresponding number of extension steps, n; also
        set *width*(b) 714 ⟩;
    $c \leftarrow ext\_bot(r)$;
    if $(c \neq min\_quarterword)$ $stack\_into\_box(b, f, c)$;
    $c \leftarrow ext\_rep(r)$;
    for $(m \leftarrow 1;\ m \leq n;\ m{+}{+})$ $stack\_into\_box(b, f, c)$;
    $c \leftarrow ext\_mid(r)$;
    if $(c \neq min\_quarterword)$ { $stack\_into\_box(b, f, c)$; $c \leftarrow ext\_rep(r)$;
      for $(m \leftarrow 1;\ m \leq n;\ m{+}{+})$ $stack\_into\_box(b, f, c)$;
    }
    $c \leftarrow ext\_top(r)$;
    if $(c \neq min\_quarterword)$ $stack\_into\_box(b, f, c)$;
    $depth(b) \leftarrow w - height(b)$;
  }
This code is used in section 710.

714.   The width of an extensible character is the width of the repeatable module. If this module does not
have positive height plus depth, we don't use any copies of it, otherwise we use as few as possible (in groups
of two if there is a middle part).

⟨ Compute the minimum suitable height, w, and the corresponding number of extension steps, n; also set
        width(b) 714 ⟩ ≡
  $c \leftarrow ext\_rep(r)$; $u \leftarrow height\_plus\_depth(f, c)$; $w \leftarrow 0$; $q \leftarrow char\_info(f, c)$;
  $width(b) \leftarrow char\_width(f, q) + char\_italic(f, q)$;

  $n \leftarrow 0$;
  if $(u > 0)$
    while $(w < v)$ { $w \leftarrow w + u$; $incr(n)$;
      if $(ext\_mid(r) \neq min\_quarterword)$ $w \leftarrow w + u$;
    }
This code is used in section 713.

715. The next subroutine is much simpler; it is used for numerators and denominators of fractions as well as for displayed operators and their limits above and below. It takes a given box b and changes it so that the new box is centered in a box of width w. The centering is done by putting \hss glue at the left and right of the list inside b, then packaging the new box; thus, the actual box might not really be centered, if it already contains infinite glue.

The given box might contain a single character whose italic correction has been added to the width of the box; in this case a compensating kern is inserted.

static pointer $rebox(\textbf{pointer } b, \textbf{scaled } w)$
$\{$ **pointer** p; $\triangleright$ temporary register for list manipulation $\triangleleft$
  internal_font_number f; $\triangleright$ font in a one-character box $\triangleleft$
  scaled v; $\triangleright$ width of a character without italic correction $\triangleleft$
  if $((width(b) \neq w) \wedge (list\_ptr(b) \neq null))$ $\{$ **if** $(type(b) \equiv vlist\_node)$ $b \leftarrow hpack(b, natural)$;
    $p \leftarrow list\_ptr(b)$;
    if $((is\_char\_node(p)) \wedge (link(p) \equiv null))$ $\{$ $f \leftarrow font(p)$;
      $v \leftarrow char\_width(f, char\_info(f, character(p)))$;
      if $(v \neq width(b))$ $link(p) \leftarrow new\_kern(width(b) - v)$;
    $\}$
    $list\_ptr(b) \leftarrow null$; $flush\_node\_list(b)$; $b \leftarrow new\_glue(ss\_glue)$; $link(b) \leftarrow p$;
    while $(link(p) \neq null)$ $p \leftarrow link(p)$;

  $\}$
  else $\{$ $width(b) \leftarrow w$; **return** b;
  $\}$
$\}$

716. Here is a subroutine that creates a new glue specification from another one that is expressed in 'mu', given the value of the math unit.

#define $mu\_mult(A)$ $nx\_plus\_y(n, A, xn\_over\_d(A, f, °200000))$

static pointer $math\_glue(\textbf{pointer } g, \textbf{scaled } m)$
$\{$ **pointer** p; $\triangleright$ the new glue specification $\triangleleft$
  int n; $\triangleright$ integer part of m $\triangleleft$
  scaled f; $\triangleright$ fraction part of m $\triangleleft$
  $n \leftarrow x\_over\_n(m, °200000)$; $f \leftarrow rem$;
  if $(f < 0)$ $\{$ $decr(n)$; $f \leftarrow f + °200000$;
  $\}$
  $p \leftarrow get\_node(glue\_spec\_size)$; $width(p) \leftarrow mu\_mult(width(g))$; $\triangleright$ convert mu to pt $\triangleleft$
  $stretch\_order(p) \leftarrow stretch\_order(g)$;
  if $(stretch\_order(p) \equiv normal)$ $stretch(p) \leftarrow mu\_mult(stretch(g))$;
  else $stretch(p) \leftarrow stretch(g)$;
  $shrink\_order(p) \leftarrow shrink\_order(g)$;
  if $(shrink\_order(p) \equiv normal)$ $shrink(p) \leftarrow mu\_mult(shrink(g))$;
  else $shrink(p) \leftarrow shrink(g)$;
  return p;
$\}$

717.   The *math_kern* subroutine removes *mu_glue* from a kern node, given the value of the math unit.

static void *math_kern*(**pointer** *p*, **scaled** *m*)
{ **int** *n*;   ▷ integer part of *m* ◁
   scaled *f*;   ▷ fraction part of *m* ◁

   if (*subtype*(*p*) ≡ *mu_glue*) { *n* ← *x_over_n*(*m*, °*200000*); *f* ← *rem*;
      if (*f* < 0) { *decr*(*n*); *f* ← *f* + °*200000*;
      }
      width(*p*) ← *mu_mult*(*width*(*p*)); *subtype*(*p*) ← *explicit*;
   }
}

718.   Sometimes it is necessary to destroy an mlist. The following subroutine empties the current list, assuming that *abs*(*mode*) ≡ *mmode*.

static void *flush_math*(**void**)
{ *flush_node_list*(*link*(*head*)); *flush_node_list*(*incompleat_noad*); *link*(*head*) ← *null*; *tail* ← *head*;
   incompleat_noad ← *null*;
}

719.   Typesetting math formulas.   TeX's most important routine for dealing with formulas is called *mlist_to_hlist*. After a formula has been scanned and represented as an mlist, this routine converts it to an hlist that can be placed into a box or incorporated into the text of a paragraph. There are three implicit parameters, passed in global variables: *cur_mlist* points to the first node or noad in the given mlist (and it might be *null*); *cur_style* is a style code; and *mlist_penalties* is *true* if penalty nodes for potential line breaks are to be inserted into the resulting hlist. After *mlist_to_hlist* has acted, *link*(*temp_head*) points to the translated hlist.

Since mlists can be inside mlists, the procedure is recursive. And since this is not part of TeX's inner loop, the program has been written in a manner that stresses compactness over efficiency.

⟨ Global variables 13 ⟩ +≡
  static pointer *cur_mlist*;   ▷ beginning of mlist to be translated ◁
  static small_number *cur_style*;   ▷ style code at current place in the list ◁
  static small_number *cur_size*;   ▷ size code corresponding to *cur_style* ◁
  static scaled *cur_mu*;   ▷ the math unit width corresponding to *cur_size* ◁
  static bool *mlist_penalties*;   ▷ should *mlist_to_hlist* insert penalties? ◁

720.   The recursion in *mlist_to_hlist* is due primarily to a subroutine called *clean_box* that puts a given noad field into a box using a given math style; *mlist_to_hlist* can call *clean_box*, which can call *mlist_to_hlist*.

The box returned by *clean_box* is "clean" in the sense that its *shift_amount* is zero.

  static void *mlist_to_hlist*(**void**);

  static pointer *clean_box*(**pointer** *p*, **small_number** *s*)
  { **pointer** *q*;   ▷ beginning of a list to be boxed ◁
    small_number *save_style*;   ▷ *cur_style* to be restored ◁
    pointer *x*;   ▷ box to be returned ◁
    pointer *r*;   ▷ temporary pointer ◁
    switch (*math_type*(*p*)) {
    case *math_char*:
      { *cur_mlist* ← *new_noad*(); *mem*[*nucleus*(*cur_mlist*)] ← *mem*[*p*];
      } **break**;
    case *sub_box*:

          if $(type(r) \equiv kern\_node)$ ▷ unneeded italic correction ◁
          { $free\_node(r, small\_node\_size)$; $link(q) \leftarrow null$;
          }
  }

This code is used in section 720.

722.   It is convenient to have a procedure that converts a *math_char* field to an "unpacked" form. The *fetch* routine sets cur_f, cur_c, and cur_i to the font code, character code, and character information bytes of a given noad field. It also takes care of issuing error messages for nonexistent characters; in such cases, $char\_exists(cur\_i)$ will be *false* after *fetch* has acted, and the field will also have been reset to *empty*.

  static void $fetch(\textbf{pointer}\ a)$ ▷ unpack the *math_char* field a ◁
  { $cur\_c \leftarrow character(a)$; $cur\_f \leftarrow fam\_fnt(fam(a) + cur\_size)$;
    if $(cur\_f \equiv null\_font)$ ⟨ Complain about an undefined family and set cur_i null 723 ⟩
    else { **if** $((qo(cur\_c) \geq font\_bc[cur\_f]) \wedge (qo(cur\_c) \leq font\_ec[cur\_f]))$
      $cur\_i \leftarrow char\_info(cur\_f, cur\_c)$;
    else $cur\_i \leftarrow null\_character$;
    if $(\neg(char\_exists(cur\_i)))$ { $char\_warning(cur\_f, qo(cur\_c))$; $math\_type(a) \leftarrow empty$;
      $cur\_i \leftarrow null\_character$;
    }
    }
  }

723.   ⟨ Complain about an undefined family and set cur_i null 723 ⟩ ≡
  { $print\_err("")$; $print\_size(cur\_size)$; $print\_char('\textvisiblespace')$; $print\_int(fam(a))$;

    $"plain\textvisiblespace TeX\textvisiblespace doesn't\textvisiblespace allow\textvisiblespace\backslash\backslash it\textvisiblespace or\textvisiblespace\backslash\backslash sl\textvisiblespace in\textvisiblespace subscripts.\textvisiblespace Proceed,"$,
    $"and\textvisiblespace I'll\textvisiblespace try\textvisiblespace to\textvisiblespace forget\textvisiblespace that\textvisiblespace I\textvisiblespace needed\textvisiblespace that\textvisiblespace character.")$; $error()$; $cur\_i \leftarrow null\_character$;
    $math\_type(a) \leftarrow empty$;
  }
This code is used in section 722.

724.   The outputs of *fetch* are placed in global variables.

⟨ Global variables 13 ⟩ +≡
  static internal_font_number cur_f;   ▷ the *font* field of a *math_char* ◁
  static quarterword cur_c;   ▷ the *character* field of a *math_char* ◁
  static four_quarters cur_i;   ▷ the *char_info* of a *math_char*, or a lig/kern instruction ◁

725.   We need to do a lot of different things, so *mlist_to_hlist* makes two passes over the given mlist.

The first pass does most of the processing: It removes "mu" spacing from glue, it recursively evaluates all subsidiary mlists so that only the top-level mlist remains to be handled, it puts fractions and square roots and such things into boxes, it attaches subscripts and superscripts, and it computes the overall height and depth of the top-level mlist so that the size of delimiters for a *left_noad* and a *right_noad* will be known. The hlist resulting from each noad is recorded in that noad's *new_hlist* field, an integer field that replaces the *nucleus* or *thickness*.

The second pass eliminates all noads and inserts the correct glue and penalties between nodes.

#**define** *new_hlist*(A) *mem*[*nucleus*(A)].i ▷ the translation of an mlist ◁

726.   Here is the overall plan of *mlist_to_hlist*, and the list of its local variables.

⟨ Declare math construction procedures 734 ⟩

  static void *mlist_to_hlist*(**void**)
  { **pointer** *mlist*;   ▷ beginning of the given list ◁
    bool *penalties*;   ▷ should penalty nodes be inserted? ◁
    small_number *style*;   ▷ the given style ◁
    small_number *save_style*;   ▷ holds *cur_style* during recursion ◁
    pointer *q*;   ▷ runs through the mlist ◁
    pointer *r*;   ▷ the most recent noad preceding *q* ◁
    small_number *r_type*;   ▷ the *type* of noad *r*, or *op_noad* if $r \equiv null$ ◁
    small_number *t*;   ▷ the effective *type* of noad *q* during the second pass ◁
    pointer *p, x, y, z*;   ▷ temporary registers for list construction ◁
    int *pen*;   ▷ a penalty to be inserted ◁
    small_number *s*;   ▷ the size of a noad to be deleted ◁
    scaled *max_h, max_d*;   ▷ maximum height and depth of the list translated so far ◁
    scaled *delta*;   ▷ offset between subscript and superscript ◁

    mlist ← *cur_mlist*; *penalties* ← *mlist_penalties*; *style* ← *cur_style*;
      ▷ tuck global parameters away as local variables ◁
    q ← *mlist*; *r* ← *null*; *r_type* ← *op_noad*; *max_h* ← 0; *max_d* ← 0;
    ⟨ Set up the values of *cur_size* and *cur_mu*, based on *cur_style* 703 ⟩;
    while ($q \neq null$) ⟨ Process node-or-noad *q* as much as possible in preparation for the second pass of
        mlist_to_hlist, then move to the next item in the mlist 727 ⟩;
    ⟨ Convert a final *bin_noad* to an *ord_noad* 729 ⟩;
    ⟨ Make a second pass over the mlist, removing all noads and inserting the proper spacing and
        penalties 760 ⟩;
  }

727.   We use the fact that no character nodes appear in an mlist, hence the field $type(q)$ is always present.

$\langle$ Process node-or-noad q as much as possible in preparation for the second pass of $mlist\_to\_hlist$, then move
        to the next item in the mlist $727 \rangle \equiv$
   { $\langle$ Do first-pass processing based on $type(q)$; **goto** $done\_with\_noad$ if a noad has been fully processed,
           goto $check\_dimensions$ if it has been translated into $new\_hlist(q)$, or **goto** $done\_with\_node$ if a
           node has been fully processed $728 \rangle$;
   $check\_dimensions$: $z \leftarrow hpack(new\_hlist(q), natural)$;

    depth(*v*) ← *delta* − *height*(*v*);
  }

737. According to the rules in the DVI file specifications, we ensure alignment between a square root sign and the rule above its nucleus by assuming that the baseline of the square-root symbol is the same as the bottom of the rule. The height of the square-root symbol will be the thickness of the rule, and the depth of the square-root symbol should exceed or equal the height-plus-depth of the nucleus plus a certain minimum clearance *clr*. The symbol will be placed so that the actual clearance is *clr* plus half the excess.

This code is used in section 743.

749. If the nucleus of an op_noad is a single character, it is to be centered vertically with respect to the axis, after first being enlarged (via a character list in the font) if we are in display style. The normal convention for placing displayed limits is to put them above and below the operator in display style.

　　The italic correction is removed from the character if there is a subscript and the limits are not being displayed. The $make\_op$ routine returns the value that should be used as an offset between subscript and superscript.

　　After $make\_op$ has acted, $subtype(q)$ will be $limits$ if and only if the limits have been set above and below the operator. In that case, $new\_hlist(q)$ will already contain the desired final box.
⟨Declare math construction procedures 734⟩ +≡

  }
This code is used in section 754.

756.   The purpose of $make\_scripts(q, delta)$ is to attach the subscript and/or superscript of noad q to the list that starts at $new\_hlist(q)$, given that the subscript and superscript aren't both empty. The superscript will appear to the right of the subscript by a given distance $delta$.

We set $shift\_down$ and $shift\_up$ to the minimum amounts to shift the baseline of subscripts and superscripts based on the given nucleus.

⟨ Declare math construction procedures 734 ⟩ +≡
  static void $make\_scripts$(**pointer** q, **scaled** $delta$)
  { **pointer** p, x, y, z;   ▷ temporary registers for box construction ◁
    scaled $shift\_up, shift\_down, clr$;   ▷ dimensions in the calculation ◁
    small_number t;   ▷ subsidiary size code ◁

    $p \leftarrow new\_hlist(q)$;
    if $(is\_char\_node(p))$ { $shift\_up \leftarrow 0$; $shift\_down \leftarrow 0$;
    }
    else { $z \leftarrow hpack(p, natural)$;
      if $(cur\_style < script\_style)$ $t \leftarrow script\_size$; **else** $t \leftarrow script\_script\_size$;
      $shift\_up \leftarrow height(z) - sup\_drop(t)$; $shift\_down \leftarrow depth(z) + sub\_drop(t)$; $list\_ptr(z) \leftarrow null$;
      $flush\_node\_list(z)$;
    }
    if $(math\_type(supscr(q)) \equiv empty)$ ⟨ Construct a subscript box x when there is no superscript 757 ⟩
    else { ⟨ Construct a superscript box x 758 ⟩;
      if $(math\_type(subscr(q)) \equiv empty)$ $shift\_amount(x) \leftarrow -shift\_up$;
      else ⟨ Construct a sub/superscript combination box x, with the superscript offset by $delta$ 759 ⟩;
    }
    if $(new\_hlist(q) \equiv null)$ $new\_hlist(q) \leftarrow x$;
    else { $p \leftarrow new\_hlist(q)$;
      while $(link(p) \neq null)$ $p \leftarrow link(p)$;
      $link(p) \leftarrow x$;
    }
  }

757.   When there is a subscript without a superscript, the top of the subscript should not exceed the baseline plus four-fifths of the x-height.

⟨ Construct a subscript box x when there is no superscript 757 ⟩ ≡
  { $x \leftarrow clean\_box(subscr(q), sub\_style(cur\_style))$; $width(x) \leftarrow width(x) + script\_space$;
    if $(shift\_down < sub1(cur\_size))$ $shift\_down \leftarrow sub1(cur\_size)$;
    $clr \leftarrow height(x) - (abs(math\_x\_height(cur\_size) * 4)/5)$;
    if $(shift\_down < clr)$ $shift\_down \leftarrow clr$;
    $shift\_amount(x) \leftarrow shift\_down$;
  }
This code is used in section 756.

758.   The bottom of a superscript should never descend below the baseline plus one-fourth of the x-height.

⟨ Construct a superscript box x 758 ⟩ ≡
  { $x \leftarrow clean\_box(supscr(q), sup\_style(cur\_style))$; $width(x) \leftarrow width(x) + script\_space$;
    if $(odd(cur\_style))$ $clr \leftarrow sup3(cur\_size)$;
    else if $(cur\_style < text\_style)$ $clr \leftarrow sup1(cur\_size)$;
    else $clr \leftarrow sup2(cur\_size)$;
    if $(shift\_up < clr)$ $shift\_up \leftarrow clr$;
    $clr \leftarrow depth(x) + (abs(math\_x\_height(cur\_size))/4)$;
    if $(shift\_up < clr)$ $shift\_up \leftarrow clr$;
  }

This code is used in section 756.

759.   When both subscript and superscript are present, the subscript must be separated from the super-script by at least four times *default_rule_thickness*. If this condition would be violated, the subscript moves down, after which both subscript and superscript move up so that the bottom of the superscript is at least as high as the baseline plus four-fifths of the x-height.

⟨ Construct a sub/superscript combination box x, with the superscript offset by *delta* 759 ⟩ ≡
  { $y \leftarrow clean\_box(subscr(q), sub\_style(cur\_style))$; $width(y) \leftarrow width(y) + script\_space$;
    if $(shift\_down < sub2(cur\_size))$ $shift\_down \leftarrow sub2(cur\_size)$;
    $clr \leftarrow 4 * default\_rule\_thickness - ((shift\_up - depth(x)) - (height(y) - shift\_down))$;
    if $(clr > 0)$ { $shift\_down \leftarrow shift\_down + clr$;
      $clr \leftarrow (abs(math\_x\_height(cur\_size) * 4)/5) - (shift\_up - depth(x))$;
      if $(clr > 0)$ { $shift\_up \leftarrow shift\_up + clr$; $shift\_down \leftarrow shift\_down - clr$;
      }
    }
    $shift\_amount(x) \leftarrow delta$;   ▷ superscript is *delta* to the right of the subscript ◁
    $p \leftarrow new\_kern((shift\_up - depth(x)) - (height(y) - shift\_down))$; $link(x) \leftarrow p$; $link(p) \leftarrow y$;
    $x \leftarrow vpack(x, natural)$; $shift\_amount(x) \leftarrow shift\_down$;
  }

This code is used in section 756.

760.   We have now tied up all the loose ends of the first pass of *mlist_to_hlist*. The second pass simply goes through and hooks everything together with the proper glue and penalties. It also handles the *left_noad* and *right_noad* that might be present, since *max_h* and *max_d* are now known. Variable p points to a node at the current end of the final hlist.

⟨ Make a second pass over the mlist, removing all noads and inserting the proper spacing and
      penalties 760 ⟩ ≡
  $p \leftarrow temp\_head$; $link(p) \leftarrow null$; $q \leftarrow mlist$; $r\_type \leftarrow 0$; $cur\_style \leftarrow style$;
  ⟨ Set up the values of *cur_size* and *cur_mu*, based on *cur_style* 703 ⟩;
  while $(q \neq null)$ { ⟨ If node q is a style node, change the style and **goto** *delete_q*; otherwise if it is not a
        noad, put it into the hlist, advance q, and **goto** *done*; otherwise set s to the size of noad q, set t
        to the associated type $(ord\_noad .. inner\_noad)$, and set *pen* to the associated penalty 761 ⟩;
    ⟨ Append inter-element spacing based on *r_type* and t 766 ⟩;
    ⟨ Append any *new_hlist* entries for q, and any appropriate penalties 767 ⟩;
    if $(type(q) \equiv right\_noad)$ $t \leftarrow open\_noad$;
    $r\_type \leftarrow t$;
  delete_q: $r \leftarrow q$; $q \leftarrow link(q)$; $free\_node(r, s)$;
  done: ;
  }

This code is used in section 726.

761.   Just before doing the big **case** switch in the second pass, the program sets up default values so that
most of the branches are short.

⟨ If node q is a style node, change the style and **goto** *delete_q*; otherwise if it is not a noad, put it into the
      hlist, advance q, and **goto** *done*; otherwise set s to the size of noad q, set t to the associated type
      (*ord_noad* .. *inner_noad*), and set *pen* to the associated penalty 761 ⟩ ≡
   $t \leftarrow ord\_noad$; $s \leftarrow noad\_size$; $pen \leftarrow inf\_penalty$;
   switch (*type*(q)) {
   case *op_noad*: **case** *open_noad*: **case** *close_noad*: **case** *punct_noad*: **case** *inner_noad*: $t \leftarrow type(q)$;
      break;
   case *bin_noad*:
      { $t \leftarrow bin\_noad$; $pen \leftarrow bin\_op\_penalty$;
      } **break**;
   case *rel_noad*:
      { $t \leftarrow rel\_noad$; $pen \leftarrow rel\_penalty$;
      } **break**;
   case *ord_noad*: **case** *vcenter_noad*: **case** *over_noad*: **case** *under_noad*: *do_nothing*; **break**;
   case *radical_noad*: $s \leftarrow radical\_noad\_size$; **break**;
   case *accent_noad*: $s \leftarrow accent\_noad\_size$; **break**;
   case *fraction_noad*: $s \leftarrow fraction\_noad\_size$; **break**;
   case *left_noad*: **case** *right_noad*: $t \leftarrow make\_left\_right(q, style, max\_d, max\_h)$; **break**;
   case *style_node*: ⟨ Change the current style and **goto** *delete_q* 763 ⟩
   case *whatsit_node*: **case** *penalty_node*: **case** *rule_node*: **case** *disc_node*: **case** *adjust_node*:
      case *ins_node*: **case** *mark_node*: **case** *glue_node*: **case** *kern_node*:
      { $link(p) \leftarrow q$; $p \leftarrow q$; $q \leftarrow link(q)$; $link(p) \leftarrow null$; **goto** *done*;
      }
   default: *confusion*("mlist3");
   }

This code is used in section 760.

762.   The *make_left_right* function constructs a left or right delimiter of the required size and returns the
value *open_noad* or *close_noad*. The *right_noad* and *left_noad* will both be based on the original *style*, so
they will have consistent sizes.

   We use the fact that $right\_noad - left\_noad \equiv close\_noad - open\_noad$.

⟨ Declare math construction procedures 734 ⟩ +≡
   static small_number *make_left_right*(**pointer** q, **small_number** *style*, **scaled** *max_d*, **scaled** *max_h*)
   { **scaled** *delta*, *delta1*, *delta2*;   ▷ dimensions used in the calculation ◁

      $cur\_style \leftarrow style$; ⟨ Set up the values of *cur_size* and *cur_mu*, based on *cur_style* 703 ⟩;
      $delta2 \leftarrow max\_d + axis\_height(cur\_size)$; $delta1 \leftarrow max\_h + max\_d - delta2$;
      if ($delta2 > delta1$) $delta1 \leftarrow delta2$;   ▷ *delta1* is max distance from axis ◁
      $delta \leftarrow (delta1/500) * delimiter\_factor$; $delta2 \leftarrow delta1 + delta1 - delimiter\_shortfall$;
      if ($delta < delta2$) $delta \leftarrow delta2$;
      $new\_hlist(q) \leftarrow var\_delimiter(delimiter(q), cur\_size, delta)$;
      return $type(q) - (left\_noad - open\_noad)$;   ▷ *open_noad* or *close_noad* ◁
   }

763.   ⟨ Change the current style and **goto** *delete_q* 763 ⟩ ≡
   { $cur\_style \leftarrow subtype(q)$; $s \leftarrow style\_node\_size$;
      ⟨ Set up the values of *cur_size* and *cur_mu*, based on *cur_style* 703 ⟩;
      goto *delete_q*;
   }

This code is used in section 761.

764.   The inter-element spacing in math formulas depends on an 8×8 table that TeX preloads as a 64-digit string. The elements of this string have the following significance:

> 0 means no space;
> 1 means a conditional thin space (`\nonscript\mskip\thinmuskip`);
> 2 means a thin space (`\mskip\thinmuskip`);
> 3 means a conditional medium space (`\nonscript\mskip\medmuskip`);
> 4 means a conditional thick space (`\nonscript\mskip\thickmuskip`);
> * means an impossible case.

This is all pretty cryptic, but *The TeXbook* explains what is supposed to happen, and the string makes it happen.

A global variable *magic_offset* is computed so that if a and b are in the range *ord_noad* .. *inner_noad*, then $str\_pool[a * 8 + b + magic\_offset]$ is the digit for spacing between noad types a and b.

If Pascal had provided a good way to preload constant arrays, this part of the program would not have been so strange.

#**define** *math_spacing*
  `"0234000122*4000133**3**344*0400400*000000234000111*1111112341011"`

765.   ⟨Global variables 13⟩ +≡
   static const int *magic_offset* ← $-9 * ord\_noad$;   ▷ used to find inter-element spacing ◁

766.   ⟨Append inter-element spacing based on *r_type* and *t* 766⟩ ≡
   if $(r\_type > 0)$ ▷ not the first noad ◁
   { **switch** $(so(math\_spacing[r\_type * 8 + t + magic\_offset]))$ {
     case '0': $x \leftarrow 0$; **break**;
     case '1':
        if $(cur\_style < script\_style)$ $x \leftarrow thin\_mu\_skip\_code$; **else** $x \leftarrow 0$; **break**;
     case '2': $x \leftarrow thin\_mu\_skip\_code$; **break**;
     case '3':
        if $(cur\_style < script\_style)$ $x \leftarrow med\_mu\_skip\_code$; **else** $x \leftarrow 0$; **break**;
     case '4':
        if $(cur\_style < script\_style)$ $x \leftarrow thick\_mu\_skip\_code$; **else** $x \leftarrow 0$; **break**;
     default: $confusion($`"mlist4"`$)$;
     }
     if $(x \neq 0)$ { $y \leftarrow math\_glue(glue\_par(x), cur\_mu)$; $z \leftarrow new\_glue(y)$; $glue\_ref\_count(y) \leftarrow null$;
        $link(p) \leftarrow z$; $p \leftarrow z$;
        $subtype(z) \leftarrow x + 1$;   ▷ store a symbolic subtype ◁
     }
   }
This code is used in section 760.

767.   We insert a penalty node after the hlist entries of noad q if *pen* is not an "infinite" penalty, and if the node immediately following q is not a penalty node or a *rel_noad* or absent entirely.

$\langle$ Append any *new_hlist* entries for q, and any appropriate penalties $767 \rangle \equiv$
   if $(new\_hlist(q) \neq null)$ { $link(p) \leftarrow new\_hlist(q);$
     do $p \leftarrow link(p);$ **while** $(\neg(link(p) \equiv null));$
   }
   if $(penalties)$
     if $(link(q) \neq null)$
       if $(pen < inf\_penalty)$ { $r\_type \leftarrow type(link(q));$
         if $(r\_type \neq penalty\_node)$
           if $(r\_type \neq rel\_noad)$ { $z \leftarrow new\_penalty(pen);$ $link(p) \leftarrow z;$ $p \leftarrow z;$
           }
       }

This code is used in section 760.

768. Alignment. It's sort of a miracle whenever \halign and \valign work, because they cut across so many of the control structures of TeX.

Therefore the present page is probably not the best place for a beginner to start reading this program; it is better to master everything else first.

Let us focus our thoughts on an example of what the input might be, in order to get some idea about how the alignment miracle happens. The example doesn't do anything useful, but it is sufficiently general to indicate all of the special cases that must be dealt with; please do not be disturbed by its apparent complexity and meaninglessness.

```
\tabskip 2pt plus 3pt
\halign to 300pt{u1#v1&
        \tabskip 1pt plus 1fil u2#v2&
        u3#v3\cr
     a1&\omit a2&\vrule\cr
     \noalign{\vskip 3pt}
     b1\span b2\cr
     \omit&c2\span\omit\cr}
```

Here's what happens:

(0) When '\halign to 300pt{' is scanned, the *scan_spec* routine places the 300pt dimension onto the *save_stack*, and an *align_group* code is placed above it. This will make it possible to complete the alignment when the matching '}' is found.

(1) The preamble is scanned next. Macros in the preamble are not expanded, except as part of a tabskip specification. For example, if u2 had been a macro in the preamble above, it would have been expanded, since TeX must look for 'minus...' as part of the tabskip glue. A "preamble list" is constructed based on the user's preamble; in our case it contains the following seven items:

\glue 2pt plus 3pt	(the tabskip preceding column 1)
\alignrecord, width $-\infty$	(preamble info for column 1)
\glue 2pt plus 3pt	(the tabskip between columns 1 and 2)
\alignrecord, width $-\infty$	(preamble info for column 2)
\glue 1pt plus 1fil	(the tabskip between columns 2 and 3)
\alignrecord, width $-\infty$	(preamble info for column 3)
\glue 1pt plus 1fil	(the tabskip following column 3)

These "alignrecord" entries have the same size as an *unset_node*, since they will later be converted into such nodes. However, at the moment they have no *type* or *subtype* fields; they have *info* fields instead, and these *info* fields are initially set to the value *end_span*, for reasons explained below. Furthermore, the alignrecord nodes have no *height* or *depth* fields; these are renamed *u_part* and *v_part*, and they point to token lists for the templates of the alignment. For example, the *u_part* field in the first alignrecord points to the token list 'u1', i.e., the template preceding the '#' for column 1.

(2) TeX now looks at what follows the \cr that ended the preamble. It is not '\noalign' or '\omit', so this input is put back to be read again, and the template 'u1' is fed to the scanner. Just before reading 'u1', TeX goes into restricted horizontal mode. Just after reading 'u1', TeX will see 'a1', and then (when the & is sensed) TeX will see 'v1'. Then TeX scans an *endv* token, indicating the end of a column. At this point an *unset_node* is created, containing the contents of the current hlist (i.e., 'u1a1v1'). The natural width of this unset node replaces the *width* field of the alignrecord for column 1; in general, the alignrecords will record the maximum natural width that has occurred so far in a given column.

(3) Since '\omit' follows the '&', the templates for column 2 are now bypassed. Again TeX goes into restricted horizontal mode and makes an *unset_node* from the resulting hlist; but this time the hlist contains simply 'a2'. The natural width of the new unset box is remembered in the *width* field of the alignrecord for column 2.

(4) A third *unset_node* is created for column 3, using essentially the mechanism that worked for column 1; this unset box contains 'u3\vrule v3'. The vertical rule in this case has running dimensions that will later extend to the height and depth of the whole first row, since each *unset_node* in a row will eventually inherit the height and depth of its enclosing box.

(5) The first row has now ended; it is made into a single unset box comprising the following seven items:

```
\glue 2pt plus 3pt
\unsetbox for 1 column: u1a1v1
\glue 2pt plus 3pt
\unsetbox for 1 column: a2
\glue 1pt plus 1fil
\unsetbox for 1 column: u3\vrule v3
\glue 1pt plus 1fil
```

The width of this unset row is unimportant, but it has the correct height and depth, so the correct baselineskip glue will be computed as the row is inserted into a vertical list.

(6) Since '\noalign' follows the current \cr, TEX appends additional material (in this case \vskip 3pt) to the vertical list. While processing this material, TEX will be in internal vertical mode, and *no_align_group* will be on *save_stack*.

(7) The next row produces an unset box that looks like this:

```
\glue 2pt plus 3pt
\unsetbox for 2 columns: u1b1v1u2b2v2
\glue 1pt plus 1fil
\unsetbox for 1 column: (empty)
\glue 1pt plus 1fil
```

The natural width of the unset box that spans columns 1 and 2 is stored in a "span node," which we will explain later; the *info* field of the alignrecord for column 1 now points to the new span node, and the *info* of the span node points to *end_span*.

(8) The final row produces the unset box

```
\glue 2pt plus 3pt
\unsetbox for 1 column: (empty)
\glue 2pt plus 3pt
\unsetbox for 2 columns: u2c2v2
\glue 1pt plus 1fil
```

A new span node is attached to the alignrecord for column 2.

(9) The last step is to compute the true column widths and to change all the unset boxes to hboxes, appending the whole works to the vertical list that encloses the \halign. The rules for deciding on the final widths of each unset column box will be explained below.

Note that as \halign is being processed, we fearlessly give up control to the rest of TEX. At critical junctures, an alignment routine is called upon to step in and do some little action, but most of the time these routines just lurk in the background. It's something like post-hypnotic suggestion.

769. We have mentioned that alignrecords contain no *height* or *depth* fields. Their *glue_sign* and *glue_order* are pre-empted as well, since it is necessary to store information about what to do when a template ends. This information is called the *extra_info* field.

#**define** $u\_part(A)$ $mem[A + height\_offset].i$ ▷ pointer to $\langle u_j \rangle$ token list ◁
#**define** $v\_part(A)$ $mem[A + depth\_offset].i$ ▷ pointer to $\langle v_j \rangle$ token list ◁
#**define** $extra\_info(A)$ $info(A + list\_offset)$ ▷ info to remember during template ◁

770.   Alignments can occur within alignments, so a small stack is used to access the alignrecord information. At each level we have a *preamble* pointer, indicating the beginning of the preamble list; a *cur_align* pointer, indicating the current position in the preamble list; a *cur_span* pointer, indicating the value of *cur_align* at the beginning of a sequence of spanned columns; a *cur_loop* pointer, indicating the tabskip glue before an alignrecord that should be copied next if the current list is extended; and the *align_state* variable, which indicates the nesting of braces so that \cr and \span and tab marks are properly intercepted. There also are pointers *cur_head* and *cur_tail* to the head and tail of a list of adjustments being moved out from horizontal mode to vertical mode.

The current values of these seven quantities appear in global variables; when they have to be pushed down, they are stored in 5-word nodes, and *align_ptr* points to the topmost such node.

#**define** *preamble*   *link*(*align_head*)   ▷ the current preamble list ◁
#**define** *align_stack_node_size*   5   ▷ number of *mem* words to save alignment states ◁

⟨ Global variables 13 ⟩ +≡
  static pointer *cur_align*;   ▷ current position in preamble list ◁
  static pointer *cur_span*;   ▷ start of currently spanned columns in preamble list ◁
  static pointer *cur_loop*;   ▷ place to copy when extending a periodic preamble ◁
  static pointer *align_ptr*;   ▷ most recently pushed-down alignment stack node ◁
  static pointer *cur_head*, *cur_tail*;   ▷ adjustment list pointers ◁

771.   The *align_state* and *preamble* variables are initialized elsewhere.

⟨ Set initial values of key variables 21 ⟩ +≡
  align_ptr ← *null*; *cur_align* ← *null*; *cur_span* ← *null*; *cur_loop* ← *null*; *cur_head* ← *null*;
  cur_tail ← *null*;

772.   Alignment stack maintenance is handled by a pair of trivial routines called *push_alignment* and *pop_alignment*.

  static void *push_alignment*(**void**)
  { **pointer** *p*;   ▷ the new alignment stack node ◁

    p ← *get_node*(*align_stack_node_size*); *link*(*p*) ← *align_ptr*; *info*(*p*) ← *cur_align*;
    llink(*p*) ← *preamble*; *rlink*(*p*) ← *cur_span*; *mem*[*p* + 2].*i* ← *cur_loop*; *mem*[*p* + 3].*i* ← *align_state*;
    info(*p* + 4) ← *cur_head*; *link*(*p* + 4) ← *cur_tail*; *align_ptr* ← *p*; *cur_head* ← *get_avail*( );
  }
  static void *pop_alignment*(**void**)
  { **pointer** *p*;   ▷ the top alignment stack node ◁

    free_avail(*cur_head*); *p* ← *align_ptr*; *cur_tail* ← *link*(*p* + 4); *cur_head* ← *info*(*p* + 4);
    align_state ← *mem*[*p* + 3].*i*; *cur_loop* ← *mem*[*p* + 2].*i*; *cur_span* ← *rlink*(*p*); *preamble* ← *llink*(*p*);
    cur_align ← *info*(*p*); *align_ptr* ← *link*(*p*); *free_node*(*p*, *align_stack_node_size*);
  }

773.   TeX has eight procedures that govern alignments: *init_align* and *fin_align* are used at the very beginning and the very end; *init_row* and *fin_row* are used at the beginning and end of individual rows; *init_span* is used at the beginning of a sequence of spanned columns (possibly involving only one column); *init_col* and *fin_col* are used at the beginning and end of individual columns; and *align_peek* is used after \cr to see whether the next item is \noalign.

We shall consider these routines in the order they are first used during the course of a complete \halign, namely *init_align*, *align_peek*, *init_row*, *init_span*, *init_col*, *fin_col*, *fin_row*, *fin_align*.

774.   When `\halign` or `\valign` has been scanned in an appropriate mode, TEX calls *init_align*, whose task is to get everything off to a good start. This mostly involves scanning the preamble and putting its information into the preamble list.

⟨ Declare the procedure called *get_preamble_token* 782 ⟩

static void *align_peek*(**void**);
static void *normal_paragraph*(**void**);

static void *init_align*(**void**)
{ **pointer** *save_cs_ptr*;   ▷ *warning_index* value for error messages ◁
  pointer *p*;   ▷ for short-term temporary use ◁

  save_cs_ptr ← *cur_cs*;   ▷ `\halign` or `\valign`, usually ◁
  push_alignment( ); *align_state* ← −1000000;   ▷ enter a new alignment level ◁
  ⟨ Check for improper alignment in displayed math 776 ⟩;
  push_nest( );   ▷ enter a new semantic level ◁
  ⟨ Change current mode to −*vmode* for `\halign`, −*hmode* for `\valign` 775 ⟩;
  scan_spec(*align_group*, *false*);
  ⟨ Scan the preamble and record it in the *preamble* list 777 ⟩;
  new_save_level(*align_group*);
  if (*every_cr* ≠ *null*) *begin_token_list*(*every_cr*, *every_cr_text*);
  align_peek( );   ▷ look for `\noalign` or `\omit` ◁
}

775.   In vertical modes, *prev_depth* already has the correct value. But if we are in *mmode* (displayed formula mode), we reach out to the enclosing vertical mode for the *prev_depth* value that produces the correct baseline calculations.

⟨ Change current mode to −*vmode* for `\halign`, −*hmode* for `\valign` 775 ⟩ ≡

  $v\_part(cur\_align) \leftarrow link(hold\_head)$
This code is used in section 777.

780. We enter '\span' into $eqtb$ with tab_mark as its command code, and with $span\_code$ as the command
modifier. This makes TeX interpret it essentially the same as an alignment delimiter like '&', yet it is
recognizably different when we need to distinguish it from a normal delimiter. It also turns out to be useful
to give a special cr_code to '\cr', and an even larger cr_cr_code to '\crcr'.
  The end of a template is represented by two "frozen" control sequences called \endtemplate. The first
has the command code $end\_template$, which is $> outer\_call$, so it will not easily disappear in the presence
of errors. The get_x_token routine converts the first into the second, which has $endv$ as its command code.

#**define** $span\_code$ 256   ▷ distinct from any character ◁
#**define** cr_code 257   ▷ distinct from $span\_code$ and from any character ◁

    ▷ put \endtemplate at the end ◁

This code is used in section 779.

785.   The tricky part about alignments is getting the templates into the scanner at the right time, and recovering control when a row or column is finished.

We usually begin a row after each \cr has been sensed, unless that \cr is followed by \noalign or by the right brace that terminates the alignment. The *align_peek* routine is used to look ahead and do the right thing; it either gets a new row started, or gets a \noalign started, or finishes off the alignment.

⟨Declare the procedure called *align_peek* 785⟩ ≡
  static void *align_peek*(**void**)
  { *restart*: $align\_state \leftarrow 1000000$;
    do *get_x_or_protected*( ); **while** $(\neg(cur\_cmd \neq spacer))$;
    if $(cur\_cmd \equiv no\_align)$ { *scan_left_brace*( ); *new_save_level*(*no_align_group*);
      if $(mode \equiv -vmode)$ *normal_paragraph*( );
    }
    else if $(cur\_cmd \equiv right\_brace)$ *fin_align*( );
    else if $((cur\_cmd \equiv car\_ret) \wedge (cur\_chr \equiv cr\_cr\_code))$ **goto** *restart*;   ▷ ignore \crcr ◁
    else { *init_row*( );   ▷ start a new row ◁
      init_col( );   ▷ start a new column and replace what we peeked at ◁
    }
  }

This code is used in section 800.

786.   To start a row (i.e., a 'row' that rhymes with 'dough' but not with 'bough'), we enter a new semantic level, copy the first tabskip glue, and change from internal vertical mode to restricted horizontal mode or vice versa. The *space_factor* and *prev_depth* are not used on this semantic level, but we clear them to zero just to be tidy.

⟨Declare the procedure called *init_span* 787⟩

  static void *init_row*(**void**)
  { *push_nest*( ); $mode \leftarrow (-hmode - vmode) - mode$;
    if $(mode \equiv -hmode)$ $space\_factor \leftarrow 0$; **else** $prev\_depth \leftarrow 0$;
    tail_append(*new_glue*(*glue_ptr*(*preamble*))); $subtype(tail) \leftarrow tab\_skip\_code + 1$;
    $cur\_align \leftarrow link(preamble)$; $cur\_tail \leftarrow cur\_head$; *init_span*(*cur_align*);
  }

787.   The parameter to *init_span* is a pointer to the alignrecord where the next column or group of columns will begin. A new semantic level is entered, so that the columns will generate a list for subsequent packaging.

⟨ Declare the procedure called *init_span* 787 ⟩ ≡
  static void *init_span*(**pointer** *p*)
  { *push_nest*( );
    if (*mode* ≡ −*hmode*) *space_factor* ← 1000;
    else { *prev_depth* ← *ignore_depth*; *normal_paragraph*( );
    }
    cur_span ← *p*;
  }

This code is used in section 786.

788.   When a column begins, we assume that *cur_cmd* is either *omit* or else the current token should be put back into the input until the ⟨*u_j*⟩ template has been scanned. (Note that *cur_cmd* might be *tab_mark* or *car_ret*.) We also assume that *align_state* is approximately 1000000 at this time. We remain in the same mode, and start the template if it is called for.

  static void *init_col*(**void**)
  { *extra_info*(*cur_align*) ← *cur_cmd*;
    if (*cur_cmd* ≡ *omit*) *align_state* ← 0;
    else { *back_input*( ); *begin_token_list*(*u_part*(*cur_align*), *u_template*);
    }   ▷ now *align_state* ≡ 1000000 ◁
  }

789.   The scanner sets *align_state* to zero when the ⟨*u_j*⟩ template ends. When a subsequent \cr or \span or tab mark occurs with *align_state* ≡ 0, the scanner activates the following code, which fires up the ⟨*v_j*⟩ template. We need to remember the *cur_chr*, which is either *cr_cr_code*, *cr_code*, *span_code*, or a character code, depending on how the column text has ended.

  This part of the program had better not be activated when the preamble to another alignment is being scanned, or when no alignment preamble is active.

⟨ Insert the ⟨*v_j*⟩ template and **goto** *restart* 789 ⟩ ≡
  { **if** ((*scanner_status* ≡ *aligning*) ∨ (*cur_align* ≡ *null*))
      fatal_error("(interwoven␣alignment␣preambles␣are␣not␣allowed)");
    cur_cmd ← *extra_info*(*cur_align*); *extra_info*(*cur_align*) ← *cur_chr*;
    if (*cur_cmd* ≡ *omit*) *begin_token_list*(*omit_template*, *v_template*);
    else *begin_token_list*(*v_part*(*cur_align*), *v_template*);
    align_state ← 1000000; **goto** *restart*;
  }

This code is used in section 342.

790.   The token list *omit_template* just referred to is a constant token list that contains the special control sequence \endtemplate only.

⟨ Initialize the special list heads and constant nodes 790 ⟩ ≡
  info(*omit_template*) ← *end_template_token*;   ▷ *link*(*omit_template*) ≡ *null* ◁

See also sections 797, 820, 981, and 988.

This code is used in section 164.

791.   When the *endv* command at the end of a $\langle v_j \rangle$ template comes through the scanner, things really start to happen; and it is the *fin_col* routine that makes them happen. This routine returns *true* if a row as well as a column has been finished.

```
static bool fin_col(void)

801.   It's time now to dismantle the preamble list and to compute the column widths. Let w_{ij} be the maximum of the natural widths of all entries that span columns i through j, inclusive. The alignrecord for column i contains w_{ii} in its *width* field, and there is also a linked list of the nonzero w_{ij} for increasing j, accessible via the *info* field; these span nodes contain the value $j - i + min\_quarterword$ in their *link* fields. The values of w_{ii} were initialized to *null_flag*, which we regard as $-\infty$.

The final column widths are defined by the formula

$$w_j = \max_{1 \le i \le j} \left(w_{ij} - \sum_{i \le k < j} (t_k + w_k) \right),$$

where t_k is the natural width of the tabskip glue between columns k and $k + 1$. However, if $w_{ij} = -\infty$ for all i in the range $1 \le i \le j$ (i.e., if every entry that involved column j also involved column $j + 1$), we let $w_j = 0$, and we zero out the tabskip glue after column j.

TeX computes these values by using the following scheme: First $w_1 = w_{11}$. Then replace w_{2j} by $\max(w_{2j}, w_{1j} - t_1 - w_1)$, for all $j > 1$. Then $w_2 = w_{22}$. Then replace w_{3j} by $\max(w_{3j}, w_{2j} - t_2 - w_2)$ for all $j > 2$; and so on. If any w_j turns out to be $-\infty$, its value is changed to zero and so is the next tabskip.

$\langle$ Go through the preamble list, determining the column widths and changing the alignrecords to dummy unset boxes $801 \rangle \equiv$
  $q \leftarrow link(preamble);$
  do {
    $flush\_list(u\_part(q));$ $flush\_list(v\_part(q));$ $p \leftarrow link(link(q));$
    if $(width(q) \equiv null\_flag)$ $\langle$ Nullify $width(q)$ and the tabskip glue following this column $802 \rangle;$
    if $(info(q) \neq end\_span)$
      $\langle$ Merge the widths in the span nodes of q with those of p, destroying the span nodes of q $803 \rangle;$
    $type(q) \leftarrow unset\_node;$ $span\_count(q) \leftarrow min\_quarterword;$ $height(q) \leftarrow 0;$ $depth(q) \leftarrow 0;$
    $glue\_order(q) \leftarrow normal;$ $glue\_sign(q) \leftarrow normal;$ $glue\_stretch(q) \leftarrow 0;$ $glue\_shrink(q) \leftarrow 0;$
#if 0   ▷ Table nodes are not implemented in the 1.2 viewer ◁
    if $(width(q) > max\_dimen)$ $x \leftarrow true;$
#endif
    $q \leftarrow p;$
  } **while** $(\neg(q \equiv null));$
This code is used in section 800.

802. $\langle$ Nullify $width(q)$ and the tabskip glue following this column $802 \rangle \equiv$
  { $width(q) \leftarrow 0;$ $r \leftarrow link(q);$ $s \leftarrow glue\_ptr(r);$
    if $(s \neq zero\_glue)$ { $add\_glue\_ref(zero\_glue);$ $delete\_glue\_ref(s);$ $glue\_ptr(r) \leftarrow zero\_glue;$
    }
  }
This code is used in section 801.

803. Merging of two span-node lists is a typical exercise in the manipulation of linearly linked data structures. The essential invariant in the following **do** { loop is that we want to dispense with node r, in q's list, and u is its successor; all nodes of p's list up to and including s have been processed, and the successor of s matches r or precedes r or follows r, according as $link(r) \equiv n$ or $link(r) > n$ or $link(r) < n$.

⟨ Merge the widths in the span nodes of q with those of p, destroying the span nodes of q 803 ⟩ ≡
```
    { t ← width(q) + width(glue_ptr(link(q)));  r ← info(q);  s ← end_span;  info(s) ← p;
      n ← min_quarterword + 1;
      do {
        width(r) ← width(r) − t;  u ← info(r);
        while (link(r) > n) {  s ← info(s);  n ← link(info(s)) + 1;
        }
        if (link(r) < n) {  info(r) ← info(s);  info(s) ← r;  decr(link(r));  s ← r;
        }
        else {  if (width(r) > width(info(s)))  width(info(s)) ← width(r);
          free_node(r, span_node_size);
        }
        r ← u;
      } while (¬(r ≡ end_span));
    }
```
This code is used in section 801.

804. Now the preamble list has been converted to a list of alternating unset boxes and tabskip glue, where the box widths are equal to the final column sizes. In case of \valign, we change the widths to heights, so that a correct error message will be produced if the alignment is overfull or underfull.

⟨ Package the preamble list, to determine the actual tabskip glue amounts, and let p point to this prototype box 804 ⟩ ≡
```
  save_ptr ← save_ptr − 2;  pack_begin_line ← −mode_line;
  if (mode ≡ −vmode) {  rule_save ← overfull_rule;  overfull_rule ← 0;
        ▷ prevent rule from being packaged ◁
    p ← hpack(preamble, saved(1), saved_hfactor(1), saved_vfactor(1), saved(0));
    overfull_rule ← rule_save;
  }
  else {  q ← link(preamble);
    do {
      height(q) ← width(q);  width(q) ← 0;  q ← link(link(q));
    } while (¬(q ≡ null));
    p ← vpack(preamble, saved(1), saved_hfactor(1), saved_vfactor(1), saved(0));  q ← link(preamble);
    do {
      width(q) ← height(q);  height(q) ← 0;  q ← link(link(q));
    } while (¬(q ≡ null));
  }
  pack_begin_line ← 0
```
This code is used in section 800.

805.   ⟨Set the glue in all the unset boxes of the current list 805⟩ ≡
  $q \leftarrow link(head)$; $s \leftarrow head$;
  while $(q \neq null)$ { **if** $(\neg is\_char\_node(q))$
      if $(type(q) \equiv unset\_node)$ ⟨Set the unset box q and the unset boxes in it 807⟩
      else if $(type(q) \equiv rule\_node)$
          ⟨Make the running dimensions in rule q extend to the boundaries of the alignment 806⟩;
      $s \leftarrow q$; $q \leftarrow link(q)$;
  }

This code is used in section 800.

806.   ⟨Make the running dimensions in rule q extend to the boundaries of the alignment 806⟩ ≡
  { **if** $(is\_running(width(q)))$ $width(q) \leftarrow width(p)$;
    if $(is\_running(height(q)))$ $height(q) \leftarrow height(p)$;
    if $(is\_running(depth(q)))$ $depth(q) \leftarrow depth(p)$;
    if $(o \neq 0)$ { $r \leftarrow link(q)$; $link(q) \leftarrow null$; $q \leftarrow hpack(q, natural)$; $shift\_amount(q) \leftarrow o$; $link(q) \leftarrow r$;
      $link(s) \leftarrow q$;
    }
  }

This code is used in section 805.

807.   The unset box q represents a row that contains one or more unset boxes, depending on how soon \cr
occurred in that row.

⟨Set the unset box q and the unset boxes in it 807⟩ ≡
  { **if** $(mode \equiv -vmode)$ { $type(q) \leftarrow hlist\_node$; $width(q) \leftarrow width(p)$;
    }
    else { $type(q) \leftarrow vlist\_node$; $height(q) \leftarrow height(p)$;
    }
    $glue\_order(q) \leftarrow glue\_order(p)$; $glue\_sign(q) \leftarrow glue\_sign(p)$; $glue\_set(q) \leftarrow glue\_set(p)$;
    $shift\_amount(q) \leftarrow o$; $r \leftarrow link(list\_ptr(q))$; $s \leftarrow link(list\_ptr(p))$;
    do {
      ⟨Set the glue in node r and change it from an unset node 808⟩;
      $r \leftarrow link(link(r))$; $s \leftarrow link(link(s))$;
    } **while** $(\neg(r \equiv null))$;
  }

This code is used in section 805.

808.   A box made from spanned columns will be followed by tabskip glue nodes and by empty boxes as if there were no spanning. This permits perfect alignment of subsequent entries, and it prevents values that depend on floating point arithmetic from entering into the dimensions of any boxes.

⟨ Set the glue in node r and change it from an unset node 808 ⟩ ≡
  $n \leftarrow span\_count(r);\ t \leftarrow width(s);\ w \leftarrow t;\ u \leftarrow hold\_head$;

    }
    height(r) ← w; *type*(r) ← *vlist_node*;
  }

This code is used in section 808.

812. We now have a completed alignment, in the list that starts at *head* and ends at *tail*. This list will be merged with the one that encloses it. (In case the enclosing mode is *mmode*, for displayed formulas, we will need to insert glue before and after the display; that part of the program will be deferred until we're more familiar with such operations.)

In restricted horizontal mode, the *clang* part of *aux* is undefined; an over-cautious Pascal runtime system may complain about this.

⟨Insert the current list into its environment 812⟩ ≡
  aux_save ← *aux*; p ← *link*(*head*); q ← *tail*; *pop_nest*( );
  if (*mode* ≡ *mmode*) ⟨Finish an alignment in a display 1206⟩

    if ($p \neq null$) *tail* ← q;
    if (*mode* ≡ *vmode*) *build_page*( );
  }

This code is used in section 800.

813. Breaking paragraphs into lines.   We come now to what is probably the most interesting algorithm of TeX: the mechanism for choosing the "best possible" breakpoints that yield the individual lines of a paragraph. TeX's line-breaking algorithm takes a given horizontal list and converts it to a sequence of boxes that are appended to the current vertical list. In the course of doing this, it creates a special data structure containing three kinds of records that are not used elsewhere in TeX. Such nodes are created while a paragraph is being processed, and they are destroyed afterwards; thus, the other parts of TeX do not need to know anything about how line-breaking is done.

The method used here is based on an approach devised by Michael F. Plass and the author in 1977, subsequently generalized and improved by the same two people in 1980. A detailed discussion appears in *Software—Practice and Experience* **11** (1981), 1119–1184, where it is shown that the line-breaking problem can be regarded as a special case of the problem of computing the shortest path in an acyclic network. The cited paper includes numerous examples and describes the history of line breaking as it has been practiced by printers through the ages. The present implementation adds two new ideas to the algorithm of 1980: Memory space requirements are considerably reduced by using smaller records for inactive nodes than for active ones, and arithmetic overflow is avoided by using "delta distances" instead of keeping track of the total distance from the beginning of the paragraph to the current point.

814.   The *line_break* procedure should be invoked only in horizontal mode; it leaves that mode and places its output into the current vlist of the enclosing vertical mode (or internal vertical mode). There is one explicit parameter: *final_widow_penalty* is the amount of additional penalty to be inserted before the final line of the paragraph.

There are also a number of implicit parameters: The hlist to be broken starts at *link*(*head*), and it is nonempty. The value of *prev_graf* in the enclosing semantic level tells where the paragraph should begin in the sequence of line numbers, in case hanging indentation or \parshape is in use; *prev_graf* is zero unless this paragraph is being continued after a displayed formula. Other implicit parameters, such as the *par_shape_ptr* and various penalties to use for hyphenation, etc., appear in *eqtb*.

After *line_break* has acted, it will have updated the current vlist and the value of *prev_graf*. Furthermore, the global variable *just_box* will point to the final box created by *line_break*, so that the width of this line can be ascertained when it is necessary to decide whether to use *above_display_skip* or *above_display_short_skip* before a displayed formula.

⟨ Global variables 13 ⟩ +≡
  static pointer *just_box*;   ▷ the *hlist_node* for the last line of the new paragraph ◁

815.   Since *line_break* is a rather lengthy procedure—sort of a small world unto itself—we must build it up little by little, somewhat more cautiously than we have done with the simpler procedures of TeX. Here is the general outline.

⟨ Declare subprocedures for *line_break* 826 ⟩
  static void *line_break*(**int** *final_widow_penalty*)
  { ⟨ Local variables for line breaking 862 ⟩
    pack_begin_line ← *mode_line*;   ▷ this is for over/underfull box messages ◁
    ⟨ Get ready to start line breaking 816 ⟩;
    ⟨ Find optimal breakpoints 863 ⟩;
    ⟨ Break the paragraph at the chosen breakpoints, justify the resulting lines to the correct widths, and
        append them to the current vertical list 876 ⟩;
    ⟨ Clean up the memory by removing the break nodes 865 ⟩;
    pack_begin_line ← 0;
  }
⟨ Declare ε-TeX procedures for use by *main_control* 1388 ⟩

816.   The first task is to move the list from *head* to *temp_head* and go into the enclosing semantic level. We also append the \parfillskip glue to the end of the paragraph, removing a space (or other glue node) if it was there, since spaces usually precede blank lines and instances of '$$'. The *par_fill_skip* is preceded by an infinite penalty, so it will never be considered as a potential breakpoint.

This code assumes that a *glue_node* and a *penalty_node* occupy the same number of *mem* words.

⟨ Get ready to start line breaking 816 ⟩ ≡
  link(*temp_head*) ← *link*(*head*);
  if (*is_char_node*(*tail*)) *tail_append*(*new_penalty*(*inf_penalty*))
  else if (*type*(*tail*) ≠ *glue_node*) *tail_append*(*new_penalty*(*inf_penalty*))
  else { *type*(*tail*) ← *penalty_node*; *delete_glue_ref*(*glue_ptr*(*tail*)); *flush_node_list*(*leader_ptr*(*tail*));
    penalty(*tail*) ← *inf_penalty*;
  }
  link(*tail*) ← *new_param_glue*(*par_fill_skip_code*); *init_cur_lang* ← *prev_graf* % °*200000*;
  init_l_hyf ← *prev_graf* / °*20000000*; *init_r_hyf* ← (*prev_graf* / °*200000*) % °*100*; *pop_nest*( );
See also sections 827, 834, and 848.

This code is used in section 815.

817.   When looking for optimal line breaks, TeX creates a "break node" for each break that is *feasible*, in the sense that there is a way to end a line at the given place without requiring any line to stretch more than a given tolerance. A break node is characterized by three things: the position of the break (which is a pointer to a *glue_node*, *math_node*, *penalty_node*, or *disc_node*); the ordinal number of the line that will follow this breakpoint; and the fitness classification of the line that has just ended, i.e., *tight_fit*, *decent_fit*, *loose_fit*, or *very_loose_fit*.

#**define** *tight_fit* 3   ▷ fitness classification for lines shrinking 0.5 to 1.0 of their shrinkability ◁
#**define** *loose_fit* 1   ▷ fitness classification for lines stretching 0.5 to 1.0 of their stretchability ◁
#**define** *very_loose_fit* 0   ▷ fitness classification for lines stretching more than their stretchability ◁
#**define** *decent_fit* 2   ▷ fitness classification for all other lines ◁

818.   The algorithm essentially determines the best possible way to achieve each feasible combination of position, line, and fitness. Thus, it answers questions like, "What is the best way to break the opening part of the paragraph so that the fourth line is a tight line ending at such-and-such a place?" However, the fact that all lines are to be the same length after a certain point makes it possible to regard all sufficiently large line numbers as equivalent, when the looseness parameter is zero, and this makes it possible for the algorithm to save space and time.

An "active node" and a "passive node" are created in *mem* for each feasible breakpoint that needs to be considered. Active nodes are three words long and passive nodes are two words long. We need active nodes only for breakpoints near the place in the paragraph that is currently being examined, so they are recycled within a comparatively short time after they are created.

819.   An active node for a given breakpoint contains six fields:

link points to the next node in the list of active nodes; the last active node has $link \equiv last\_active$.

break_node points to the passive node associated with this breakpoint.

line_number is the number of the line that follows this breakpoint.

fitness is the fitness classification of the line ending at this breakpoint.

type is either *hyphenated* or *unhyphenated*, depending on whether this breakpoint is a *disc_node*.

total_demerits is the minimum possible sum of demerits over all lines leading from the beginning of the
       paragraph to this breakpoint.

The value of $link(active)$ points to the first active node on a linked list of all currently active nodes. This list
is in order by *line_number*, except that nodes with $line\_number > easy\_line$ may be in any order relative
to each other.

#**define** *active_node_size* 3   ▷ number of words in active nodes ◁
#**define** *fitness*(A) *subtype*(A)   ▷ *very_loose_fit* .. *tight_fit* on final line for this break ◁
#**define** *break_node*(A) *rlink*(A)   ▷ pointer to the corresponding passive node ◁
#**define** *line_number*(A) *llink*(A)   ▷ line that begins at this breakpoint ◁
#**define** *total_demerits*(A) $mem[A+2].i$ ▷ the quantity that TEX minimizes ◁
#**define** *unhyphenated* 0   ▷ the *type* of a normal active break node ◁
#**define** *hyphenated* 1   ▷ the *type* of an active node that breaks at a *disc_node* ◁
#**define** *last_active* *active*   ▷ the active list ends where it begins ◁

820.   ⟨ Initialize the special list heads and constant nodes 790 ⟩ +≡
    $type(last\_active) \leftarrow hyphenated$; $line\_number(last\_active) \leftarrow max\_halfword$; $subtype(last\_active) \leftarrow 0$;
       ▷ the *subtype* is never examined by the algorithm ◁

821.   The passive node for a given breakpoint contains only four fields:

link points to the passive node created just before this one, if any, otherwise it is *null*.

cur_break points to the position of this breakpoint in the horizontal list for the paragraph being broken.

prev_break points to the passive node that should precede this one in an optimal path to this breakpoint.

serial is equal to n if this passive node is the nth one created during the current pass. (This field is used
       only when printing out detailed statistics about the line-breaking calculations.)

There is a global variable called *passive* that points to the most recently created passive node. Another
global variable, *printed_node*, is used to help print out the paragraph when detailed information about the
line-breaking computation is being displayed.

#**define** *passive_node_size* 2   ▷ number of words in passive nodes ◁
#**define** *cur_break*(A) *rlink*(A)   ▷ in passive node, points to position of this breakpoint ◁
#**define** *prev_break*(A) *llink*(A)   ▷ points to passive node that should precede this one ◁
#**define** *serial*(A) *info*(A)   ▷ serial number for symbolic identification ◁

⟨ Global variables 13 ⟩ +≡
   static pointer *passive*;   ▷ most recent node on passive list ◁
   static pointer *printed_node*;   ▷ most recent node that has been printed ◁
   static halfword *pass_number*;   ▷ the number of passive nodes allocated on this pass ◁

822. The active list also contains "delta" nodes that help the algorithm compute the badness of individual lines. Such nodes appear only between two active nodes, and they have $type \equiv delta\_node$. If p and r are active nodes and if q is a delta node between them, so that $link(p) \equiv q$ and $link(q) \equiv r$, then q tells the space difference between lines in the horizontal list that start after breakpoint p and lines that start after breakpoint r. In other words, if we know the length of the line that starts after p and ends at our current position, then the corresponding length of the line that starts after r is obtained by adding the amounts in node q. A delta node contains six scaled numbers, since it must record the net change in glue stretchability with respect to all orders of infinity. The natural width difference appears in $mem[q+1].sc$; the stretch differences in units of pt, fil, fill, and filll appear in $mem[q+2 \mathinner{..} q+5].sc$; and the shrink difference appears in $mem[q+6].sc$. The $subtype$ field of a delta node is not used.

#**define** $delta\_node\_size$ 7   ▷ number of words in a delta node ◁
#**define** $delta\_node$ 2   ▷ $type$ field in a delta node ◁

823. As the algorithm runs, it maintains a set of six delta-like registers for the length of the line following the first active breakpoint to the current position in the given hlist. When it makes a pass through the active list, it also maintains a similar set of six registers for the length following the active breakpoint of current interest. A third set holds the length of an empty line (namely, the sum of \leftskip and \rightskip); and a fourth set is used to create new delta nodes.

When we pass a delta node we want to do operations like

$$\textbf{for } k \leftarrow 1 \textbf{ to } 6 \textbf{ do } cur\_active\_width[k] \leftarrow cur\_active\_width[k] + mem[q+k].sc;$$

and we want to do this without the overhead of **for** loops. The do_all_six macro makes such six-tuples convenient.

#**define** $do\_all\_six(A)$ $A(1)$; $A(2)$; $A(3)$; $A(4)$; $A(5)$; $A(6)$

⟨ Global variables 13 ⟩ +≡

824.   Let's state the principles of the delta nodes more precisely and concisely, so that the following programs will be less obscure. For each legal breakpoint p in the paragraph, we define two quantities $\alpha(p)$ and $\beta(p)$ such that the length of material in a line from breakpoint p to breakpoint q is $\gamma + \beta(q) - \alpha(p)$, for some fixed γ. Intuitively, $\alpha(p)$ and $\beta(q)$ are the total length of material from the beginning of the paragraph to a point "after" a break at p and to a point "before" a break at q; and γ is the width of an empty line, namely the length contributed by \leftskip and \rightskip.

Suppose, for example, that the paragraph consists entirely of alternating boxes and glue skips; let the boxes have widths $x_1 \ldots x_n$ and let the skips have widths $y_1 \ldots y_n$, so that the paragraph can be represented by $x_1 y_1 \ldots x_n y_n$. Let p_i be the legal breakpoint at y_i; then $\alpha(p_i) = x_1 + y_1 + \cdots + x_i + y_i$, and $\beta(p_i) = x_1 + y_1 + \cdots + x_i$. To check this, note that the length of material from p_2 to p_5, say, is $\gamma + x_3 + y_3 + x_4 + y_4 + x_5 = \gamma + \beta(p_5) - \alpha(p_2)$.

The quantities α, β, γ involve glue stretchability and shrinkability as well as a natural width. If we were to compute $\alpha(p)$ and $\beta(p)$ for each p, we would need multiple precision arithmetic, and the multiprecise numbers would have to be kept in the active nodes. TeX avoids this problem by working entirely with relative differences or "deltas." Suppose, for example, that the active list contains $a_1\, \delta_1\, a_2\, \delta_2\, a_3$, where the a's are active breakpoints and the δ's are delta nodes. Then $\delta_1 = \alpha(a_1) - \alpha(a_2)$ and $\delta_2 = \alpha(a_2) - \alpha(a_3)$. If the line breaking algorithm is currently positioned at some other breakpoint p, the *active_width* array contains the value $\gamma + \beta(p) - \alpha(a_1)$. If we are scanning through the list of active nodes and considering a tentative line that runs from a_2 to p, say, the *cur_active_width* array will contain the value $\gamma + \beta(p) - \alpha(a_2)$. Thus, when we move from a_2 to a_3, we want to add $\alpha(a_2) - \alpha(a_3)$ to *cur_active_width*; and this is just δ_2, which appears in the active list between a_2 and a_3. The *background* array contains γ. The *break_width* array will be used to calculate values of new delta nodes when the active list is being updated.

825.   Glue nodes in a horizontal list that is being paragraphed are not supposed to include "infinite" shrinkability; that is why the algorithm maintains four registers for stretching but only one for shrinking. If the user tries to introduce infinite shrinkability, the shrinkability will be reset to finite and an error message will be issued. A boolean variable *no_shrink_error_yet* prevents this error message from appearing more than once per paragraph.

#**define** *check_shrinkage*(A)

  background[6] ← *shrink*(*q*) + *shrink*(*r*);

828. A pointer variable *cur_p* runs through the given horizontal list as we look for breakpoints. This variable is global, since it is used both by *line_break* and by its subprocedure *try_break*.

Another global variable called *threshold* is used to determine the feasibility of individual lines: Breakpoints are feasible if there is a way to reach them without creating lines whose badness exceeds *threshold*. (The badness is compared to *threshold* before penalties are added, so that penalty values do not affect the feasibility of breakpoints, except that no break is allowed when the penalty is 10000 or more.) If *threshold* is 10000 or more, all legal breaks are considered feasible, since the *badness* function specified above never returns a value greater than 10000.

Up to three passes might be made through the paragraph in an attempt to find at least one set of feasible breakpoints. On the first pass, we have *threshold* ≡ *pretolerance* and *second_pass* ≡ *final_pass* ≡ *false*. If this pass fails to find a feasible solution, *threshold* is set to *tolerance*, *second_pass* is set *true*, and an attempt is made to hyphenate as many words as possible. If that fails too, we add *emergency_stretch* to the background stretchability and set *final_pass* ≡ *true*.

⟨Global variables 13⟩ +≡
  static pointer *cur_p*;   ▷ the current breakpoint under consideration ◁

  static bool *final_pass*;   ▷ is this our final attempt to break this paragraph? ◁
  static int *threshold*;   ▷ maximum badness on feasible lines ◁

829.   The heart of the line-breaking procedure is '*try_break*', a subroutine that tests if the current break-point *cur_p* is feasible, by running through the active list to see what lines of text can be made from active nodes to *cur_p*. If feasible breaks are possible, new break nodes are created. If *cur_p* is too far from an active node, that node is deactivated.

The parameter *pi* to *try_break* is the penalty associated with a break at *cur_p*; we have $pi \equiv eject\_penalty$ if the break is forced, and $pi \equiv inf\_penalty$ if the break is illegal.

The other parameter, *break_type*, is set to *hyphenated* or *unhyphenated*, depending on whether or not the current break is at a *disc_node*. The end of a paragraph is also regarded as '*hyphenated*'; this case is distinguishable by the condition $cur\_p \equiv null$.

     goto *resume*;

  }

This code is used in section 829.

833.   As we consider various ways to end a line at cur_p, in a given line number class, we keep track of the best total demerits known, in an array with one entry for each of the fitness classifications. For example, $minimal\_demerits[tight\_fit]$ contains the fewest total demerits of feasible line breaks ending at cur_p with a $tight\_fit$ line; $best\_place[tight\_fit]$ points to the passive node for the break before cur_p that achieves such an optimum; and $best\_pl\_line[tight\_fit]$ is the $line\_number$ field in the active node corresponding to $best\_place[tight\_fit]$. When no feasible break sequence is known, the $minimal\_demerits$ entries will be equal to $awful\_bad$, which is $2^{30} - 1$. Another variable, $minimum\_demerits$, keeps track of the smallest value in the $minimal\_demerits$ array.

   $minimal\_demerits[very\_loose\_fit] \leftarrow awful\_bad$;

835.   The first part of the following code is part of TeX's inner loop, so we don't want to waste any time. The current active node, namely node r, contains the line number that will be considered next. At the end of the list we have arranged the data structure so that $r \equiv last\_active$ and $line\_number(last\_active) > old\_l$.

⟨ If a line number class has ended, create new active nodes for the best feasible breaks in that class; then
       return if $r \equiv last\_active$, otherwise compute the new $line\_width$ 835 ⟩ ≡
   { $l \leftarrow line\_number(r)$;
     if $(l > old\_l)$ {   ▷ now we are no longer in the inner loop ◁
       if $((minimum\_demerits < awful\_bad) \wedge ((old\_l \neq easy\_line) \vee (r \equiv last\_active)))$
         ⟨ Create new active nodes for the best feasible breaks just found 836 ⟩;
       if $(r \equiv last\_active)$ **goto** end;
       ⟨ Compute the new line width 850 ⟩;
     }
   }
This code is used in section 829.

836. It is not necessary to create new active nodes having *minimal_demerits* greater than *minimum_demerits* + *abs*(*adj_demerits*), since such active nodes will never be chosen in the final paragraph breaks. This observation allows us to omit a substantial number of feasible breakpoints from further consideration.

⟨ Create new active nodes for the best feasible breaks just found 836 ⟩ ≡
  { **if** (*no_break_yet*) ⟨ Compute the values of *break_width* 837 ⟩;
    ⟨ Insert a delta node to prepare for breaks at *cur_p* 843 ⟩;
    if (*abs*(*adj_demerits*) ≥ *awful_bad* − *minimum_demerits*) *minimum_demerits* ← *awful_bad* − 1;
    else *minimum_demerits* ← *minimum_demerits* + *abs*(*adj_demerits*);
    for (*fit_class* ← *very_loose_fit*; *fit_class* ≤ *tight_fit*; *fit_class* ++) {
        if (*minimal_demerits*[*fit_class*] ≤ *minimum_demerits*)
        ⟨ Insert a new active node from *best_place*[*fit_class*] to *cur_p* 845 ⟩;
        minimal_demerits[*fit_class*] ← *awful_bad*;
      }
    minimum_demerits ← *awful_bad*; ⟨ Insert a delta node to prepare for the next active node 844 ⟩;
  }

This code is used in section 835.

837. When we insert a new active node for a break at *cur_p*, suppose this new node is to be placed just before active node a; then we essentially want to insert 'δ *cur_p* δ'' before a, where $\delta = \alpha(a) - \alpha(cur\_p)$ and $\delta' = \alpha(cur\_p) - \alpha(a)$ in the notation explained above. The *cur_active_width* array now holds $\gamma + \beta(cur\_p) - \alpha(a)$; so δ can be obtained by subtracting *cur_active_width* from the quantity $\gamma + \beta(cur\_p) - \alpha(cur\_p)$. The latter quantity can be regarded as the length of a line "from *cur_p* to *cur_p*"; we call it the *break_width* at *cur_p*.

The *break_width* is usually negative, since it consists of the background (which is normally zero) minus the width of nodes following *cur_p* that are eliminated after a break. If, for example, node *cur_p* is a glue node, the width of this glue is subtracted from the background; and we also look ahead to eliminate all subsequent glue and penalty and kern and math nodes, subtracting their widths as well.

Kern nodes do not disappear at a line break unless they are *explicit*.

#**define** *set_break_width_to_background*(*A*) *break_width*[*A*] ← *background*[*A*]

⟨ Compute the values of *break_width* 837 ⟩ ≡

    $break\_width[6] \leftarrow break\_width[6] - shrink(v)$;
  }

This code is used in section 837.

839.   When cur_p is a discretionary break, the length of a line "from cur_p to cur_p" has to be defined properly so that the other calculations work out. Suppose that the pre-break text at cur_p has length l_0, the post-break text has length l_1, and the replacement text has length l. Suppose also that q is the node following the replacement text. Then length of a line from cur_p to q will be computed as $\gamma + \beta(q) - \alpha(cur\_p)$, where $\beta(q) = \beta(cur\_p) - l_0 + l$. The actual length will be the background plus l_1, so the length from cur_p to cur_p should be $\gamma + l_0 + l_1 - l$. If the post-break text of the discretionary is empty, a break may also discard q; in that unusual case we subtract the length of q and any other nodes that will be discarded after the discretionary break.

  The value of l_0 need not be computed, since $line\_break$ will put it into the global variable $disc\_width$ before calling try_break.

      else $print\_int(serial(prev\_break(passive)))$;
   }

This code is used in section 845.

847.   The length of lines depends on whether the user has specified \parshape or \hangindent. If par_shape_ptr is not null, it points to a $(2n + 1)$-word record in mem, where the $info$ in the first word contains the value of n, and the other $2n$ words contain the left margins and line lengths for the first n lines of the paragraph; the specifications for line n apply to all subsequent lines. If $par\_shape\_ptr \equiv null$, the shape of the paragraph depends on the value of $n \equiv hang\_after$; if $n \geq 0$, hanging indentation takes place on lines $n+1$, $n+2$, ..., otherwise it takes place on lines 1, ..., $|n|$. When hanging indentation is active, the left margin is $hang\_indent$, if $hang\_indent \geq 0$, else it is 0; the line length is $hsize - |hang\_indent|$. The normal setting is $par\_shape\_ptr \equiv null$, $hang\_after \equiv 1$, and $hang\_indent \equiv 0$. Note that if $hang\_indent \equiv 0$, the value of $hang\_after$ is irrelevant.

⟨ Global variables 13 ⟩ +≡
   static halfword $easy\_line$;   ▷ line numbers $> easy\_line$ are equivalent in break nodes ◁
   static halfword $last\_special\_line$;   ▷ line numbers $> last\_special\_line$ all have the same width ◁
   static scaled $first\_width$;
      ▷ the width of all lines $\leq last\_special\_line$, if no \parshape has been specified ◁
   static scaled $second\_width$;   ▷ the width of all lines $> last\_special\_line$ ◁
   static scaled $first\_indent$;   ▷ left margin to go with $first\_width$ ◁
   static scaled $second\_indent$;   ▷ left margin to go with $second\_width$ ◁

848.   We compute the values of *easy_line* and the other local variables relating to line length when the
line_break procedure is initializing itself.

⟨ Get ready to start line breaking 816 ⟩ +≡

  if (*par_shape_ptr* ≡ *null*)

      if (*hang_indent* ≥ 0) *second_indent* ← *hang_indent*;

      else *second_indent* ← 0;

    }

  }

This code is used in section 848.

850.   When we come to the following code, we have just encountered the first active node *r* whose
line_number field contains *l*. Thus we want to compute the length of the *l*th line of the current paragraph.
Furthermore, we want to set *old_l* to the last number in the class of line numbers equivalent to *l*.

⟨ Compute the new line width 850 ⟩ ≡

  if (*l* > *easy_line*) { *line_width* ← *second_width*; *old_l* ← *max_halfword* − 1;

  }

  else { *old_l* ← *l*;

    if (*l* > *last_special_line*) *line_width* ← *second_width*;

    else if (*par_shape_ptr* ≡ *null*) *line_width* ← *first_width*;

    else *line_width* ← *mem*[*par_shape_ptr* + 2 ∗ *l*].*sc*;

  }

This code is used in section 835.

851.   The remaining part of *try_break* deals with the calculation of demerits for a break from r to *cur_p*.
   The first thing to do is calculate the badness, b. This value will always be between zero and *inf_bad* + 1;
the latter value occurs only in the case of lines from r to *cur_p* that cannot shrink enough to fit the necessary
width. In such cases, node r will be deactivated. We also deactivate node r when a break at *cur_p* is forced,
since future breaks must go through a forced break.

⟨ Consider the demerits for a line from r to *cur_p*; deactivate node r if it should no longer be active; then
       goto *resume* if a line from r to *cur_p* is infeasible, otherwise record a new feasible break 851 ⟩ ≡
   { *artificial_demerits* ← *false*;
     shortfall ← *line_width* − *cur_active_width*[1];   ▷ we're this much too short ◁
     if (*shortfall* > 0) ⟨ Set the value of b to the badness for stretching the line, and compute the
             corresponding *fit_class* 852 ⟩
     else ⟨ Set the value of b to the badness for shrinking the line, and compute the corresponding
             fit_class 853 ⟩;
     if ((*b* > *inf_bad*) ∨ (*pi* ≡ *eject_penalty*)) ⟨ Prepare to deactivate node r, and **goto** *deactivate* unless
             there is a reason to consider lines of text from r to *cur_p* 854 ⟩
     else { *prev_r* ← *r*;
       if (*b* > *threshold*) **goto** *resume*;
       node_r_stays_active ← *true*;
     }
     ⟨ Record a new feasible break 855 ⟩;
     if (*node_r_stays_active*) **goto** *resume*;   ▷ *prev_r* has been set to r ◁
   deactivate: ⟨ Deactivate node r 860 ⟩;
   }

This code is used in section 829.

852.   When   a   line   must   stretch,   the   available   stretchability   can   be   found   in   the   subarray
cur_active_width[2 . . 5], in units of points, fil, fill, and filll.
   The present section is part of TeX's inner loop, and it is most often performed when the badness is infinite;
therefore it is worth while to make a quick test for large width excess and small stretchability, before calling
the *badness* subroutine.

⟨ Set the value of b to the badness for stretching the line, and compute the corresponding *fit_class* 852 ⟩ ≡
   if ((*cur_active_width*[3] ≠ 0) ∨ (*cur_active_width*[4] ≠ 0) ∨ (*cur_active_width*[5] ≠ 0)) { *b* ← 0;
     fit_class ← *decent_fit*;   ▷ infinite stretch ◁
   }
   else { **if** (*shortfall* > 7230584)
       if (*cur_active_width*[2] < 1663497) { *b* ← *inf_bad*; *fit_class* ← *very_loose_fit*; **goto** *done1*;
       }
     b ← *badness*(*shortfall*, *cur_active_width*[2]);
     if (*b* > 12)
       if (*b* > 99) *fit_class* ← *very_loose_fit*;
       else *fit_class* ← *loose_fit*;
     else *fit_class* ← *decent_fit*;
   done1: ;
   }

This code is used in section 851.

853.   Shrinkability is never infinite in a paragraph; we can shrink the line from r to cur_p by at most $cur\_active\_width[6]$.

⟨ Set the value of b to the badness for shrinking the line, and compute the corresponding fit_class 853 ⟩ ≡
  { **if** $(-shortfall > cur\_active\_width[6])$ $b \leftarrow inf\_bad + 1$;
    else $b \leftarrow badness(-shortfall, cur\_active\_width[6])$;
    if $(b > 12)$ $fit\_class \leftarrow tight\_fit$; **else** $fit\_class \leftarrow decent\_fit$;
  }

This code is used in section 851.

854.   During the final pass, we dare not lose all active nodes, lest we lose touch with the line breaks already found. The code shown here makes sure that such a catastrophe does not happen, by permitting overfull boxes as a last resort. This particular part of TEX was a source of several subtle bugs before the correct program logic was finally discovered; readers who seek to "improve" TEX should therefore think thrice before daring to make any changes here.

⟨ Prepare to deactivate node r, and **goto** $deactivate$ unless there is a reason to consider lines of text from r
      to cur_p 854 ⟩ ≡
  { **if** $(final\_pass \wedge (minimum\_demerits \equiv awful\_bad) \wedge (link(r) \equiv last\_active) \wedge (prev\_r \equiv active))$
      $artificial\_demerits \leftarrow true$;   ▷ set demerits zero, this break is forced ◁
    else if $(b > threshold)$ **goto** $deactivate$;
    $node\_r\_stays\_active \leftarrow false$;
  }

This code is used in section 851.

855.   When we get to this part of the code, the line from r to cur_p is feasible, its badness is b, and its fitness classification is fit_class. We don't want to make an active node for this break yet, but we will compute the total demerits and record them in the $minimal\_demerits$ array, if such a break is the current champion among all ways to get to cur_p in a given line-number class and fitness class.

⟨ Record a new feasible break 855 ⟩ ≡
  if $(artificial\_demerits)$ $d \leftarrow 0$;
  else ⟨ Compute the demerits, d, from r to cur_p 859 ⟩;
#**ifdef** STAT
  if $(tracing\_paragraphs > 0)$ ⟨ Print a symbolic description of this feasible break 856 ⟩;
#**endif**
  $d \leftarrow d + total\_demerits(r)$;   ▷ this is the minimum total demerits from the beginning to cur_p via r ◁
  if $(d \leq minimal\_demerits[fit\_class])$ { $minimal\_demerits[fit\_class] \leftarrow d$;
    $best\_place[fit\_class] \leftarrow break\_node(r)$; $best\_pl\_line[fit\_class] \leftarrow l$;
    if $(d < minimum\_demerits)$ $minimum\_demerits \leftarrow d$;
  }

This code is used in section 851.

856. ⟨Print a symbolic description of this feasible break 856⟩ ≡
  { **if** (*printed_node* ≠ *cur_p*)
      ⟨Print the list between *printed_node* and *cur_p*, then set *printed_node*: ← *cur_p* 857⟩;
    print_nl("@");
    if (*cur_p* ≡ *null*) *print_esc*("par");

      else *print_esc*("math");
    }
    print("␣via␣@@");
    if (*break_node*(*r*) ≡ *null*) *print_char*('0');
    else *print_int*(*serial*(*break_node*(*r*)));
    print("␣b=");
    if (*b* > *inf_bad*) *print_char*('*'); **else** *print_int*(*b*);
    print("␣p="); *print_int*(*pi*); *print*("␣d=");
    if (*artificial_demerits*) *print_char*('*'); **else** *print_int*(*d*);
  }

This code is used in section 855.

857. ⟨Print the list between *printed_node* and *cur_p*, then set *printed_node*: ← *cur_p* 857⟩ ≡
  { *print_nl*("");
    if (*cur_p* ≡ *null*) *short_display*(*link*(*printed_node*));
    else { *save_link* ← *link*(*cur_p*); *link*(*cur_p*) ← *null*; *print_nl*("");
      short_display(*link*(*printed_node*)); *link*(*cur_p*) ← *save_link*;
    }
    printed_node ← *cur_p*;
  }

This code is used in section 856.

858. When the data for a discretionary break is being displayed, we will have printed the *pre_break* and
post_break lists; we want to skip over the third list, so that the discretionary data will not appear twice.
The following code is performed at the very end of *try_break*.

⟨Update the value of *printed_node* for symbolic displays 858⟩ ≡
  if (*cur_p* ≡ *printed_node*)
    if (*cur_p* ≠ *null*)
      if (*type*(*cur_p*) ≡ *disc_node*) { *t* ← *replace_count*(*cur_p*);
        while (*t* > 0) { *decr*(*t*); *printed_node* ← *link*(*printed_node*);
        }
      }

This code is used in section 829.

859. ⟨Compute the demerits, d, from r to cur_p 859⟩ ≡

  { $d \leftarrow line\_penalty + b$;
    if $(abs(d) \geq 10000)\ d \leftarrow 100000000$; **else** $d \leftarrow d * d$;
    if $(pi \neq 0)$
      if $(pi > 0)\ d \leftarrow d + pi * pi$;
      else if $(pi > eject\_penalty)\ d \leftarrow d - pi * pi$;
    if $((break\_type \equiv hyphenated) \wedge (type(r) \equiv hyphenated))$
      if $(cur\_p \neq null)\ d \leftarrow d + double\_hyphen\_demerits$;
      else $d \leftarrow d + final\_hyphen\_demerits$;
    if $(abs(fit\_class - fitness(r)) > 1)\ d \leftarrow d + adj\_demerits$;
  }

This code is used in section 855.

860. When an active node disappears, we must delete an adjacent delta node if the active node was at the beginning or the end of the active list, or if it was surrounded by delta nodes. We also must preserve the property that cur_active_width represents the length of material from $link(prev\_r)$ to cur_p.

#**define** $combine\_two\_deltas(A)$ $mem[prev\_r + A].sc \leftarrow mem[prev\_r + A].sc + mem[r + A].sc$
#**define** $downdate\_width(A)$ $cur\_active\_width[A] \leftarrow cur\_active\_width[A] - mem[prev\_r + A].sc$

⟨Deactivate node r 860⟩ ≡
  $link(prev\_r) \leftarrow link(r)$; $free\_node(r, active\_node\_size)$;
  if $(prev\_r \equiv active)$ ⟨Update the active widths, since the first active node has been deleted 861⟩
  else if $(type(prev\_r) \equiv delta\_node)$ { $r \leftarrow link(prev\_r)$;
    if $(r \equiv last\_active)$ { $do\_all\_six(downdate\_width)$; $link(prev\_prev\_r) \leftarrow last\_active$;
      $free\_node(prev\_r, delta\_node\_size)$; $prev\_r \leftarrow prev\_prev\_r$;
    }
    else if $(type(r) \equiv delta\_node)$ { $do\_all\_six(update\_width)$; $do\_all\_six(combine\_two\_deltas)$;
      $link(prev\_r) \leftarrow link(r)$; $free\_node(r, delta\_node\_size)$;
    }
  }

This code is used in section 851.

861. The following code uses the fact that $type(last\_active) \neq delta\_node$. If the active list has just become empty, we do not need to update the $active\_width$ array, since it will be initialized when an active node is next inserted.

#**define** $update\_active(A)$ $active\_width[A] \leftarrow active\_width[A] + mem[r + A].sc$

⟨Update the active widths, since the first active node has been deleted 861⟩ ≡
  { $r \leftarrow link(active)$;
    if $(type(r) \equiv delta\_node)$ { $do\_all\_six(update\_active)$; $do\_all\_six(copy\_to\_cur\_active)$;
      $link(active) \leftarrow link(r)$; $free\_node(r, delta\_node\_size)$;
    }
  }

This code is used in section 860.

862. Breaking paragraphs into lines, continued. So far we have gotten a little way into the *line_break* routine, having covered its important *try_break* subroutine. Now let's consider the rest of the process.

The main loop of *line_break* traverses the given hlist, starting at *link*(*temp_head*), and calls *try_break* at each legal breakpoint. A variable called *auto_breaking* is set to true except within math formulas, since glue nodes are not legal breakpoints when they appear in formulas.

The current node of interest in the hlist is pointed to by *cur_p*. Another variable, *prev_p*, is usually one step behind *cur_p*, but the real meaning of *prev_p* is this: If $type(cur\_p) \equiv glue\_node$ then *cur_p* is a legal breakpoint if and only if *auto_breaking* is true and *prev_p* does not point to a glue node, penalty node, explicit kern node, or math node.

The following declarations provide for a few other local variables that are used in special calculations.

⟨ Local variables for line breaking 862 ⟩ ≡
    bool *auto_breaking*;   ▷ is node *cur_p* outside a formula? ◁
    pointer *prev_p*;   ▷ helps to determine when glue nodes are breakpoints ◁
    pointer *q, r, s, prev_s*;   ▷ miscellaneous nodes of temporary interest ◁
    internal_font_number *f*;   ▷ used when calculating character widths ◁
See also section 893.

This code is used in section 815.

863.   The 'loop' in the following code is performed at most thrice per call of *line_break*, since it is actually a pass over the entire paragraph.

⟨ Find optimal breakpoints 863 ⟩ ≡
　threshold ← *pretolerance*;
　if (*threshold* ≥ 0) {
#ifdef STAT
　　if (*tracing_paragraphs* > 0) { *begin_diagnostic*( ); *print_nl*("@firstpass"); }
#endif
　　second_pass ← *false*; *final_pass* ← *false*;
　}
　else { *threshold* ← *tolerance*; *second_pass* ← *true*; *final_pass* ← (*emergency_stretch* ≤ 0);
#ifdef STAT
　　if (*tracing_paragraphs* > 0) *begin_diagnostic*( );
#endif
　}
　loop { **if** (*threshold* > *inf_bad*) *threshold* ← *inf_bad*;

　　if (¬*second_pass*) {
#ifdef STAT
　　　if (*tracing_paragraphs* > 0) *print_nl*("@secondpass");
#endif
　　　threshold ← *tolerance*; *second_pass* ← *true*; *final_pass* ← (*emergency_stretch* ≤ 0);
　　}　　▷ if at first you don't succeed, . . . ◁
　　else {
#ifdef STAT
　　　if (*tracing_paragraphs* > 0) *print_nl*("@emergencypass");
#endif
　　　background[2] ← *background*[2] + *emergency_stretch*; *final_pass* ← *true*;
　　}
　}
done:
#ifdef STAT
　if (*tracing_paragraphs* > 0) { *end_diagnostic*(*true*); *normalize_selector*( );
　}
#endif

This code is used in section 815.

864.   The active node that represents the starting point does not need a corresponding passive node.

#**define** $store\_background(A)$ $active\_width[A] \leftarrow background[A]$

⟨ Create an active breakpoint representing the beginning of the paragraph 864 ⟩ ≡
    $q \leftarrow get\_node(active\_node\_size)$; $type(q) \leftarrow unhyphenated$; $fitness(q) \leftarrow decent\_fit$;
    $link(q) \leftarrow last\_active$; $break\_node(q) \leftarrow null$; $line\_number(q) \leftarrow prev\_graf + 1$; $total\_demerits(q) \leftarrow 0$;
    $link(active) \leftarrow q$; $do\_all\_six(store\_background)$;
    $passive \leftarrow null$; $printed\_node \leftarrow temp\_head$; $pass\_number \leftarrow 0$; $font\_in\_short\_display \leftarrow null\_font$
This code is used in section 863.

865.   ⟨ Clean up the memory by removing the break nodes 865 ⟩ ≡
    $q \leftarrow link(active)$;
    while $(q \neq last\_active)$ { $cur\_p \leftarrow link(q)$;
        if $(type(q) \equiv delta\_node)$ $free\_node(q, delta\_node\_size)$;
        else $free\_node(q, active\_node\_size)$;
        $q \leftarrow cur\_p$;
    }
    $q \leftarrow passive$;
    while $(q \neq null)$ { $cur\_p \leftarrow link(q)$; $free\_node(q, passive\_node\_size)$; $q \leftarrow cur\_p$;
    }
This code is used in sections 815 and 863.

866.   Here is the main switch in the *line_break* routine, where legal breaks are determined. As we move through the hlist, we need to keep the *active_width* array up to date, so that the badness of individual lines is readily calculated by *try_break*. It is convenient to use the short name *act_width* for the component of active width that represents real width as opposed to glue.

#define *act_width*   *active_width*[1]   ▷ length from first active node to current node ◁
#define *kern_break*
       { **if** (¬*is_char_node*(*link*(*cur_p*)) ∧ *auto_breaking*)
          if (*type*(*link*(*cur_p*)) ≡ *glue_node*) *try_break*(0, *unhyphenated*);
        act_width ← *act_width* + *width*(*cur_p*);
       }

⟨ Call *try_break* if *cur_p* is a legal breakpoint; on the second pass, also try to hyphenate the next word, if
    cur_p is a glue node; then advance *cur_p* to the next node of the paragraph that could possibly be a
    legal breakpoint 866 ⟩ ≡
  { **if** (*is_char_node*(*cur_p*)) ⟨ Advance *cur_p* to the node following the present string of characters 867 ⟩;
   switch (*type*(*cur_p*)) {
   case *hlist_node*: **case** *vlist_node*: **case** *rule_node*: *act_width* ← *act_width* + *width*(*cur_p*); **break**;

   prev_p ← *cur_p*; *cur_p* ← *link*(*cur_p*);
  done5: ;
  }
This code is used in section 863.

867.   The code that passes over the characters of words in a paragraph is part of TeX's inner loop, so it has been streamlined for speed. We use the fact that '`\parfillskip`' glue appears at the end of each paragraph; it is therefore unnecessary to check if $link(cur\_p) \equiv null$ when cur_p is a character node.

⟨ Advance cur_p to the node following the present string of characters 867 ⟩ ≡
  { $prev\_p \leftarrow cur\_p$;
    do {
       $f \leftarrow font(cur\_p)$; $act\_width \leftarrow act\_width + char\_width(f, char\_info(f, character(cur\_p)))$;
       $cur\_p \leftarrow link(cur\_p)$;
    } **while** $(\neg(\neg is\_char\_node(cur\_p)))$;
  }

This code is used in section 866.

868.   When node cur_p is a glue node, we look at $prev\_p$ to see whether or not a breakpoint is legal at cur_p, as explained above.

⟨ If node cur_p is a legal breakpoint, call try_break; then update the active widths by including the glue in
       $glue\_ptr(cur\_p)$ 868 ⟩ ≡
  if $(auto\_breaking)$ { **if** $(is\_char\_node(prev\_p))$ $try\_break(0, unhyphenated)$;
    else if $(precedes\_break(prev\_p))$ $try\_break(0, unhyphenated)$;
    else if $((type(prev\_p) \equiv kern\_node) \wedge (subtype(prev\_p) \neq explicit))$ $try\_break(0, unhyphenated)$;
  }
  $check\_shrinkage(glue\_ptr(cur\_p))$; $q \leftarrow glue\_ptr(cur\_p)$; $act\_width \leftarrow act\_width + width(q)$;
  $active\_width[2 + stretch\_order(q)] \leftarrow active\_width[2 + stretch\_order(q)] + stretch(q)$;
  $active\_width[6] \leftarrow active\_width[6] + shrink(q)$

This code is used in section 866.

869.   The following code knows that discretionary texts contain only character nodes, kern nodes, box nodes, rule nodes, and ligature nodes.

⟨ Try to break after a discretionary fragment, then **goto** $done5$ 869 ⟩ ≡
  { $s \leftarrow pre\_break(cur\_p)$; $disc\_width \leftarrow 0$;
    if $(s \equiv null)$ $try\_break(ex\_hyphen\_penalty, hyphenated)$;
    else { **do** {
        ⟨ Add the width of node s to $disc\_width$ 870 ⟩;
        $s \leftarrow link(s)$;
      } **while** $(\neg(s \equiv null))$;
      $act\_width \leftarrow act\_width + disc\_width$; $try\_break(hyphen\_penalty, hyphenated)$;
      $act\_width \leftarrow act\_width - disc\_width$;
    }
    $r \leftarrow replace\_count(cur\_p)$; $s \leftarrow link(cur\_p)$;
    while $(r > 0)$ { ⟨ Add the width of node s to act_width 871 ⟩;
      $decr(r)$; $s \leftarrow link(s)$;
    }
    $prev\_p \leftarrow cur\_p$; $cur\_p \leftarrow s$; **goto** $done5$;
  }

This code is used in section 866.

870.   ⟨Add the width of node s to $disc\_width$ 870⟩ ≡
  if $(is\_char\_node(s))$ { $f \leftarrow font(s)$;
    $disc\_width \leftarrow disc\_width + char\_width(f, char\_info(f, character(s)))$;
  }
  else
    switch $(type(s))$ {
    case $ligature\_node$:
      { $f \leftarrow font(lig\_char(s))$;
        $disc\_width \leftarrow disc\_width + char\_width(f, char\_info(f, character(lig\_char(s))))$;
      } **break**;
    case $hlist\_node$: **case** $vlist\_node$: **case** $rule\_node$: **case** $kern\_node$:
      $disc\_width \leftarrow disc\_width + width(s)$; **break**;
    default: $confusion("disc3")$;
    }
This code is used in section 869.

871.   ⟨Add the width of node s to act_width 871⟩ ≡
  if $(is\_char\_node(s))$ { $f \leftarrow font(s)$; $act\_width \leftarrow act\_width + char\_width(f, char\_info(f, character(s)))$;
  }
  else
    switch $(type(s))$ {
    case $ligature\_node$:
      { $f \leftarrow font(lig\_char(s))$;
        $act\_width \leftarrow act\_width + char\_width(f, char\_info(f, character(lig\_char(s))))$;
      } **break**;
    case $hlist\_node$: **case** $vlist\_node$: **case** $rule\_node$: **case** $kern\_node$:
      $act\_width \leftarrow act\_width + width(s)$; **break**;
    default: $confusion("disc4")$;
    }
This code is used in section 869.

872.   The forced line break at the paragraph's end will reduce the list of breakpoints so that all active nodes represent breaks at $cur\_p \equiv null$. On the first pass, we insist on finding an active node that has the correct "looseness." On the final pass, there will be at least one active node, and we will match the desired looseness as well as we can.

The global variable $best\_bet$ will be set to the active node for the best way to break the paragraph, and a few other variables are used to help determine what is best.

⟨Global variables 13⟩ +≡
  static pointer $best\_bet$;   ▷ use this passive node and its predecessors ◁
  static int $fewest\_demerits$;   ▷ the demerits associated with $best\_bet$ ◁
  static halfword $best\_line$;   ▷ line number following the last line of the new paragraph ◁
  static int $actual\_looseness$;   ▷ the difference between $line\_number(best\_bet)$ and the optimum $best\_line$ ◁
  static int $line\_diff$;   ▷ the difference between the current line number and the optimum $best\_line$ ◁

873. ⟨Try the final line break at the end of the paragraph, and **goto** *done* if the desired breakpoints have been found 873⟩ ≡
{ *try_break*(*eject_penalty*, *hyphenated*);
  if (*link*(*active*) ≠ *last_active*) { ⟨Find an active node with fewest demerits 874⟩;
    if (*looseness* ≡ 0) **goto** *done*;
    ⟨Find the best active node for the desired looseness 875⟩;
    if ((*actual_looseness* ≡ *looseness*) ∨ *final_pass*) **goto** *done*;
  }
}

This code is used in section 863.

874. ⟨Find an active node with fewest demerits 874⟩ ≡
  r ← *link*(*active*); *fewest_demerits* ← *awful_bad*;
  do {
    if (*type*(*r*) ≠ *delta_node*)
      if (*total_demerits*(*r*) < *fewest_demerits*) { *fewest_demerits* ← *total_demerits*(*r*); *best_bet* ← *r*;
      }
    r ← *link*(*r*);
  } **while** (¬(*r* ≡ *last_active*));
  best_line ← *line_number*(*best_bet*)

This code is used in section 873.

875. The adjustment for a desired looseness is a slightly more complicated version of the loop just considered. Note that if a paragraph is broken into segments by displayed equations, each segment will be subject to the looseness calculation, independently of the other segments.

⟨Find the best active node for the desired looseness 875⟩ ≡
  { *r* ← *link*(*active*); *actual_looseness* ← 0;
    do {
      if (*type*(*r*) ≠ *delta_node*) { *line_diff* ← *line_number*(*r*) − *best_line*;
        if (((*line_diff* < *actual_looseness*) ∧ (*looseness* ≤ *line_diff*)) ∨
              ((*line_diff* > *actual_looseness*) ∧ (*looseness* ≥ *line_diff*))) { *best_bet* ← *r*;
          actual_looseness ← *line_diff*; *fewest_demerits* ← *total_demerits*(*r*);
        }
        else if ((*line_diff* ≡ *actual_looseness*) ∧ (*total_demerits*(*r*) < *fewest_demerits*)) { *best_bet* ← *r*;
          fewest_demerits ← *total_demerits*(*r*);
        }
      }
      r ← *link*(*r*);
    } **while** (¬(*r* ≡ *last_active*));
    best_line ← *line_number*(*best_bet*);
  }

This code is used in section 873.

876. Once the best sequence of breakpoints has been found (hurray), we call on the procedure *post_line_break* to finish the remainder of the work. (By introducing this subprocedure, we are able to keep *line_break* from getting extremely long.)

⟨Break the paragraph at the chosen breakpoints, justify the resulting lines to the correct widths, and append them to the current vertical list 876⟩ ≡
  post_line_break(*final_widow_penalty*)

This code is used in section 815.

877. The total number of lines that will be set by *post_line_break* is *best_line − prev_graf − 1*. The last breakpoint is specified by *break_node(best_bet)*, and this passive node points to the other breakpoints via the *prev_break* links. The finishing-up phase starts by linking the relevant passive nodes in forward order, changing *prev_break* to *next_break*. (The *next_break* fields actually reside in the same memory space as the *prev_break* fields did, but we give them a new name because of their new significance.) Then the lines are justified, one by one.

#**define** *next_break   prev_break*   ▷ new name for *prev_break* after links are reversed ◁

⟨ Declare subprocedures for *line_break* 826 ⟩ +≡

  static void *post_line_break*(**int** *final_widow_penalty*)

  { **pointer** *q, r, s*;   ▷ temporary registers for list manipulation ◁

    bool *disc_break*;   ▷ was the current break at a discretionary node? ◁

    bool *post_disc_break*;   ▷ and did it have a nonempty post-break part? ◁

    scaled *cur_width*;   ▷ width of line number *cur_line* ◁

    scaled *cur_indent*;   ▷ left margin of line number *cur_line* ◁

    quarterword *t*;   ▷ used for replacement counts in discretionary nodes ◁

    int *pen*;   ▷ use when calculating penalties between lines ◁

    halfword *cur_line*;   ▷ the current line number being justified ◁

    ⟨ Reverse the links of the relevant passive nodes, setting *cur_p* to the first breakpoint 878 ⟩

    cur_line ← prev_graf + 1;

    do {

       ⟨ Justify the line ending at breakpoint *cur_p*, and append it to the current vertical list, together with associated penalties and other insertions 880 ⟩;

       incr(cur_line); *cur_p ← next_break(cur_p)*;

       if (*cur_p ≠ null*)

          if (¬*post_disc_break*) ⟨ Prune unwanted nodes at the beginning of the next line 879 ⟩;

    } **while** (¬(*cur_p ≡ null*));

    if ((*cur_line ≠ best_line*) ∨ (*link(temp_head) ≠ null*)) *confusion*("line␣breaking");

    prev_graf ← best_line − 1;

  }

878. The job of reversing links in a list is conveniently regarded as the job of taking items off one stack and putting them on another. In this case we take them off a stack pointed to by *q* and having *prev_break* fields; we put them on a stack pointed to by *cur_p* and having *next_break* fields. Node *r* is the passive node being moved from stack to stack.

⟨ Reverse the links of the relevant passive nodes, setting *cur_p* to the first breakpoint 878 ⟩ ≡

  q ← break_node(best_bet); *cur_p ← null*;

  do {

     r ← q; *q ← prev_break(q)*; *next_break(r) ← cur_p*; *cur_p ← r*;

  } **while** (¬(*q ≡ null*));

This code is used in section 877.

879.   Glue and penalty and kern and math nodes are deleted at the beginning of a line, except in the anomalous case that the node to be deleted is actually one of the chosen breakpoints. Otherwise the pruning done here is designed to match the lookahead computation in *try_break*, where the *break_width* values are computed for non-discretionary breakpoints.

⟨ Prune unwanted nodes at the beginning of the next line 879 ⟩ ≡
  { $r \leftarrow temp\_head$;
    loop { $q \leftarrow link(r)$;
      if $(q \equiv cur\_break(cur\_p))$ **goto** *done1*;   ▷ $cur\_break(cur\_p)$ is the next breakpoint ◁
        ▷ now q cannot be *null* ◁
      if $(is\_char\_node(q))$ **goto** *done1*;
      if $(non\_discardable(q))$ **goto** *done1*;
      if $(type(q) \equiv kern\_node)$
        if $(subtype(q) \neq explicit)$ **goto** *done1*;
      $r \leftarrow q$;   ▷ now $type(q) \equiv glue\_node$, $kern\_node$, $math\_node$, or $penalty\_node$ ◁
    }
  done1:
    if $(r \neq temp\_head)$ { $link(r) \leftarrow null$; $flush\_node\_list(link(temp\_head))$; $link(temp\_head) \leftarrow q$;
    }
  }

This code is used in section 877.

880.   The current line to be justified appears in a horizontal list starting at $link(temp\_head)$ and ending at $cur\_break(cur\_p)$. If $cur\_break(cur\_p)$ is a glue node, we reset the glue to equal the *right_skip* glue; otherwise we append the *right_skip* glue at the right. If $cur\_break(cur\_p)$ is a discretionary node, we modify the list so that the discretionary break is compulsory, and we set *disc_break* to *true*. We also append the *left_skip* glue at the left of the line, unless it is zero.

⟨ Justify the line ending at breakpoint *cur_p*, and append it to the current vertical list, together with
    associated penalties and other insertions 880 ⟩ ≡
  ⟨ Modify the end of the line to reflect the nature of the break and to include \rightskip; also set the
    proper value of *disc_break* 881 ⟩;
  ⟨ Put the \leftskip glue at the left and detach this line 887 ⟩;
  ⟨ Call the packaging subroutine, setting *just_box* to the justified box 889 ⟩;
  ⟨ Append the new box to the current vertical list, followed by the list of special nodes taken out of the
    box by the packager 888 ⟩;
  ⟨ Append a penalty node, if a nonzero penalty is appropriate 890 ⟩

This code is used in section 877.

881.   At the end of the following code, q will point to the final node on the list about to be justified.

⟨ Modify the end of the line to reflect the nature of the break and to include \rightskip; also set the
       proper value of $disc\_break$ 881 ⟩ ≡
  $q \leftarrow cur\_break(cur\_p)$; $disc\_break \leftarrow false$; $post\_disc\_break \leftarrow false$;
  if $(q \neq null)$ ▷ q cannot be a $char\_node$ ◁
     if $(type(q) \equiv glue\_node)$ { $delete\_glue\_ref(glue\_ptr(q))$; $glue\_ptr(q) \leftarrow right\_skip$;
        $subtype(q) \leftarrow right\_skip\_code + 1$; $add\_glue\_ref(right\_skip)$; **goto** $done$;
     }
     else { **if** $(type(q) \equiv disc\_node)$ ⟨ Change discretionary to compulsory and set $disc\_break$: ← $true$ 882 ⟩
        else if $((type(q) \equiv math\_node) \vee (type(q) \equiv kern\_node))$ $width(q) \leftarrow 0$;
     }
  else { $q \leftarrow temp\_head$;
     while $(link(q) \neq null)$ $q \leftarrow link(q)$;
  }
  ⟨ Put the \rightskip glue after node q 886 ⟩;
  $done$:
This code is used in section 880.

882.   ⟨ Change discretionary to compulsory and set $disc\_break$: ← $true$ 882 ⟩ ≡
  { $t \leftarrow replace\_count(q)$; ⟨ Destroy the t nodes following q, and make r point to the following node 883 ⟩;
     if $(post\_break(q) \neq null)$ ⟨ Transplant the post-break list 884 ⟩;
     if $(pre\_break(q) \neq null)$ ⟨ Transplant the pre-break list 885 ⟩;
     $link(q) \leftarrow r$; $disc\_break \leftarrow true$;
  }
This code is used in section 881.

883.   ⟨ Destroy the t nodes following q, and make r point to the following node 883 ⟩ ≡
  if $(t \equiv 0)$ $r \leftarrow link(q)$;
  else { $r \leftarrow q$;
     while $(t > 1)$ { $r \leftarrow link(r)$; $decr(t)$;
     }
     $s \leftarrow link(r)$; $r \leftarrow link(s)$; $link(s) \leftarrow null$; $flush\_node\_list(link(q))$; $set\_replace\_count(q, 0)$;
  }
This code is used in section 882.

884.   We move the post-break list from inside node q to the main list by reattaching it just before the
present node r, then resetting r.

⟨ Transplant the post-break list 884 ⟩ ≡
  { $s \leftarrow post\_break(q)$;
     while $(link(s) \neq null)$ $s \leftarrow link(s)$;
     $link(s) \leftarrow r$; $r \leftarrow post\_break(q)$; $post\_break(q) \leftarrow null$; $post\_disc\_break \leftarrow true$;
  }
This code is used in section 882.

885.   We move the pre-break list from inside node q to the main list by reattaching it just after the present node q, then resetting q.

⟨ Transplant the pre-break list 885 ⟩ ≡
   { $s \leftarrow pre\_break(q)$; $link(q) \leftarrow s$;
      while $(link(s) \neq null)$ $s \leftarrow link(s)$;
      $pre\_break(q) \leftarrow null$; $q \leftarrow s$;
   }

This code is used in section 882.

886.   ⟨ Put the \rightskip glue after node q 886 ⟩ ≡
   $r \leftarrow new\_param\_glue(right\_skip\_code)$; $link(r) \leftarrow link(q)$; $link(q) \leftarrow r$; $q \leftarrow r$

This code is used in section 881.

887.   The following code begins with q at the end of the list to be justified. It ends with q at the beginning of that list, and with $link(temp\_head)$ pointing to the remainder of the paragraph, if any.

⟨ Put the \leftskip glue at the left and detach this line 887 ⟩ ≡
   $r \leftarrow link(q)$; $link(q) \leftarrow null$; $q \leftarrow link(temp\_head)$; $link(temp\_head) \leftarrow r$;
   if $(left\_skip \neq zero\_glue)$ { $r \leftarrow new\_param\_glue(left\_skip\_code)$; $link(r) \leftarrow q$; $q \leftarrow r$;
   }

This code is used in section 880.

888.   ⟨ Append the new box to the current vertical list, followed by the list of special nodes taken out of
         the box by the packager 888 ⟩ ≡
   $append\_to\_vlist(just\_box)$;
   if $(adjust\_head \neq adjust\_tail)$ { $link(tail) \leftarrow link(adjust\_head)$; $tail \leftarrow adjust\_tail$;
   }
   $adjust\_tail \leftarrow null$

This code is used in section 880.

889.   Now q points to the hlist that represents the current line of the paragraph. We need to compute the appropriate line width, pack the line into a box of this size, and shift the box by the appropriate amount of indentation.

⟨ Call the packaging subroutine, setting $just\_box$ to the justified box 889 ⟩ ≡
   if $(cur\_line > last\_special\_line)$ { $cur\_width \leftarrow second\_width$; $cur\_indent \leftarrow second\_indent$;
   }
   else if $(par\_shape\_ptr \equiv null)$ { $cur\_width \leftarrow first\_width$; $cur\_indent \leftarrow first\_indent$;
   }
   else { $cur\_width \leftarrow mem[par\_shape\_ptr + 2 * cur\_line].sc$;
      $cur\_indent \leftarrow mem[par\_shape\_ptr + 2 * cur\_line - 1].sc$;
   }
   $adjust\_tail \leftarrow adjust\_head$;
   $just\_box \leftarrow hpack(q, cur\_width, 0, 0, exactly)$; $shift\_amount(just\_box) \leftarrow cur\_indent$

This code is used in section 880.

890. Penalties between the lines of a paragraph come from club and widow lines, from the *inter_line_penalty* parameter, and from lines that end at discretionary breaks. Breaking between lines of a two-line paragraph gets both club-line and widow-line penalties. The local variable *pen* will be set to the sum of all relevant penalties for the current line, except that the final line is never penalized.

⟨ Append a penalty node, if a nonzero penalty is appropriate 890 ⟩ ≡
    if (*cur_line* + 1 ≠ *best_line*) { *pen* ← *inter_line_penalty*;
      if (*cur_line* ≡ *prev_graf* + 1) *pen* ← *pen* + *club_penalty*;
      if (*cur_line* + 2 ≡ *best_line*) *pen* ← *pen* + *final_widow_penalty*;
      if (*disc_break*) *pen* ← *pen* + *broken_penalty*;
      if (*pen* ≠ 0) { *r* ← *new_penalty*(*pen*); *link*(*tail*) ← *r*; *tail* ← *r*;
      }
    }

This code is used in section 880.

891.   Pre-hyphenation.   When the line-breaking routine is unable to find a feasible sequence of break-points, it makes a second pass over the paragraph, attempting to hyphenate the hyphenatable words. The goal of hyphenation is to insert discretionary material into the paragraph so that there are more potential places to break.

The general rules for hyphenation are somewhat complex and technical, because we want to be able to hyphenate words that are preceded or followed by punctuation marks, and because we want the rules to work for languages other than English. We also must contend with the fact that hyphens might radically alter the ligature and kerning structure of a word.

A sequence of characters will be considered for hyphenation only if it belongs to a "potentially hyphenatable part" of the current paragraph. This is a sequence of nodes $p_0 p_1 \ldots p_m$ where p_0 is a glue node, $p_1 \ldots p_{m-1}$ are either character or ligature or whatsit or implicit kern nodes, and p_m is a glue or penalty or insertion or adjust or mark or whatsit or explicit kern node. (Therefore hyphenation is disabled by boxes, math formulas, and discretionary nodes already inserted by the user.) The ligature nodes among $p_1 \ldots p_{m-1}$ are effectively expanded into the original non-ligature characters; the kern nodes and whatsits are ignored. Each character c is now classified as either a nonletter (if $lc\_code(c) \equiv 0$), a lowercase letter (if $lc\_code(c) \equiv c$), or an uppercase letter (otherwise); an uppercase letter is treated as if it were $lc\_code(c)$ for purposes of hyphenation. The characters generated by $p_1 \ldots p_{m-1}$ may begin with nonletters; let c_1 be the first letter that is not in the middle of a ligature. Whatsit nodes preceding c_1 are ignored; a whatsit found after c_1 will be the terminating node p_m. All characters that do not have the same font as c_1 will be treated as nonletters. The *hyphen_char* for that font must be between 0 and 255, otherwise hyphenation will not be attempted. TeX looks ahead for as many consecutive letters $c_1 \ldots c_n$ as possible; however, n must be less than 64, so a character that would otherwise be c_{64} is effectively not a letter. Furthermore c_n must not be in the middle of a ligature. In this way we obtain a string of letters $c_1 \ldots c_n$ that are generated by nodes $p_a \ldots p_b$, where $1 \leq a \leq b + 1 \leq m$. If $n \geq l\_hyf + r\_hyf$, this string qualifies for hyphenation; however, uc_hyph must be positive, if c_1 is uppercase.

The hyphenation process takes place in three stages. First, the candidate sequence $c_1 \ldots c_n$ is found; then potential positions for hyphens are determined by referring to hyphenation tables; and finally, the nodes $p_a \ldots p_b$ are replaced by a new sequence of nodes that includes the discretionary breaks found.

Fortunately, we do not have to do all this calculation very often, because of the way it has been taken out of TeX's inner loop. For example, when the second edition of the author's 700-page book *Seminumerical Algorithms* was typeset by TeX, only about 1.2 hyphenations needed to be tried per paragraph, since the line breaking algorithm needed to use two passes on only about 5 per cent of the paragraphs.

⟨ Initialize for hyphenating a paragraph 891 ⟩ ≡
```
  {
#ifdef INIT
    if (trie_not_ready) init_trie( );
#endif
    cur_lang ← init_cur_lang; l_hyf ← init_l_hyf; r_hyf ← init_r_hyf; set_hyph_index;
  }
```
This code is used in section 863.

892.   The letters $c_1 \ldots c_n$ that are candidates for hyphenation are placed into an array called hc; the number n is placed into hn; pointers to nodes p_{a-1} and p_b in the description above are placed into variables ha and hb; and the font number is placed into hf.

⟨Global variables 13⟩ +≡

    static int16_t $hc[66]$;   ▷ word to be hyphenated ◁

    static int hn;   ▷ the number of positions occupied in hc; not always a **small_number** ◁

    static pointer ha, hb;   ▷ nodes $ha \mathinner{\ldotp\ldotp} hb$ should be replaced by the hyphenated result ◁

    static internal_font_number hf;   ▷ font number of the letters in hc ◁

    static int16_t $hu[64]$;   ▷ like hc, before conversion to lowercase ◁

    static int hyf_char;   ▷ hyphen character of the relevant font ◁

    static ASCII_code $cur\_lang, init\_cur\_lang$;   ▷ current hyphenation table of interest ◁

    static int $l\_hyf, r\_hyf, init\_l\_hyf, init\_r\_hyf$;   ▷ limits on fragment sizes ◁

    static halfword hyf_bchar;   ▷ boundary character after c_n ◁

893.   Hyphenation routines need a few more local variables.

⟨Local variables for line breaking 862⟩ +≡

    small_number j;   ▷ an index into hc or hu ◁

    int c;   ▷ character being considered for hyphenation ◁

894.   When the following code is activated, the *line_break* procedure is in its second pass, and *cur_p* points to a glue node.

    static void $hyphenate\_word(\textbf{void})$

900. Post-hyphenation.   If a hyphen may be inserted between $hc[j]$ and $hc[j+1]$, the hyphenation procedure will set $hyf[j]$ to some small odd number. But before we look at TeX's hyphenation procedure, which is independent of the rest of the line-breaking algorithm, let us consider what we will do with the hyphens it finds, since it is better to work on this part of the program before forgetting what ha and hb, etc., are all about.

⟨ Global variables 13 ⟩ +≡
  static int8_t $hyf[65]$;   ▷ odd values indicate discretionary hyphens ◁
  static pointer $init\_list$;   ▷ list of punctuation characters preceding the word ◁
  static bool $init\_lig$;   ▷ does $init\_list$ represent a ligature? ◁
  static bool $init\_lft$;   ▷ if so, did the ligature involve a left boundary? ◁

901.   ⟨ Local variables for hyphenation 901 ⟩ ≡
  int i, j, l;   ▷ indices into hc or hu ◁
  pointer q, r, s;   ▷ temporary registers for list manipulation ◁
  halfword $bchar$;   ▷ boundary character of hyphenated word, or non_char ◁
See also sections 912, 922, and 929.

This code is used in section 895.

902.   TeX will never insert a hyphen that has fewer than \lefthyphenmin letters before it or fewer than \righthyphenmin after it; hence, a short word has comparatively little chance of being hyphenated. If no hyphens have been found, we can save time by not having to make any changes to the paragraph.

⟨ If no hyphens were found, **return** 902 ⟩ ≡
  for $(j \leftarrow l\_hyf;\ j \leq hn - r\_hyf;\ j{+}{+})$
    if $(odd(hyf[j]))$ **goto** $found1$;
  return; $found1$:

This code is used in section 895.

903. If hyphens are in fact going to be inserted, TeX first deletes the subsequence of nodes between *ha* and *hb*. An attempt is made to preserve the effect that implicit boundary characters and punctuation marks had on ligatures inside the hyphenated word, by storing a left boundary or preceding character in *hu*[0] and by storing a possible right boundary in *bchar*. We set $j \leftarrow 0$ if *hu*[0] is to be part of the reconstruction; otherwise $j \leftarrow 1$. The variable *s* will point to the tail of the current hlist, and *q* will point to the node following *hb*, so that things can be hooked up after we reconstitute the hyphenated word.

⟨ Replace nodes *ha* .. *hb* by a sequence of nodes that includes the discretionary hyphens 903 ⟩ ≡

 while $(link(s) \neq ha)$ $s \leftarrow link(s)$;
 $j \leftarrow 0$; **goto** *common_ending*;
found2: $s \leftarrow ha$; $j \leftarrow 0$; $hu[0] \leftarrow 256$; $init\_lig \leftarrow false$; $init\_list \leftarrow null$;
common_ending: $flush\_node\_list(r)$;
 ⟨ Reconstitute nodes for the hyphenated word, inserting discretionary hyphens 913 ⟩;
 $flush\_list(init\_list)$
This code is used in section 895.

904. We must now face the fact that the battle is not over, even though the hyphens have been found: The process of reconstituting a word can be nontrivial because ligatures might change when a hyphen is present. *The TeXbook* discusses the difficulties of the word "difficult", and the discretionary material surrounding a hyphen can be considerably more complex than that. Suppose `abcdef` is a word in a font for which the only ligatures are `bc`, `cd`, `de`, and `ef`. If this word permits hyphenation between `b` and `c`, the two patterns with and without hyphenation are `a b - cd ef` and `a bc de f`. Thus the insertion of a hyphen might cause effects to ripple arbitrarily far into the rest of the word. A further complication arises if additional hyphens appear together with such rippling, e.g., if the word in the example just given could also be hyphenated between `c` and `d`; TeX avoids this by simply ignoring the additional hyphens in such weird cases.

Still further complications arise in the presence of ligatures that do not delete the original characters. When punctuation precedes the word being hyphenated, TeX's method is not perfect under all possible scenarios, because punctuation marks and letters can propagate information back and forth. For example, suppose the original pre-hyphenation pair `*a` changes to `*y` via a `|=:` ligature, which changes to `xy` via a `=:|` ligature; if $p_{a-1} = $ `x` and $p_a = $ `y`, the reconstitution procedure isn't smart enough to obtain `xy` again. In such cases the font designer should include a ligature that goes from `xa` to `xy`.

905.   The processing is facilitated by a subroutine called *reconstitute*. Given a string of characters $x_j \ldots x_n$, there is a smallest index $m \geq j$ such that the "translation" of $x_j \ldots x_n$ by ligatures and kerning has the form $y_1 \ldots y_t$ followed by the translation of $x_{m+1} \ldots x_n$, where $y_1 \ldots y_t$ is some nonempty sequence of character, ligature, and kern nodes. We call $x_j \ldots x_m$ a "cut prefix" of $x_j \ldots x_n$. For example, if $x_1 x_2 x_3 = \mathtt{fly}$, and if the font contains 'fl' as a ligature and a kern between 'fl' and 'y', then $m = 2$, $t = 2$, and y_1 will be a ligature node for 'fl' followed by an appropriate kern node y_2. In the most common case, x_j forms no ligature with x_{j+1} and we simply have $m = j$, $y_1 = x_j$. If $m < n$ we can repeat the procedure on $x_{m+1} \ldots x_n$ until the entire translation has been found.

The *reconstitute* function returns the integer m and puts the nodes $y_1 \ldots y_t$ into a linked list starting at *link*(*hold_head*), getting the input $x_j \ldots x_n$ from the *hu* array. If $x_j = 256$, we consider x_j to be an implicit left boundary character; in this case j must be strictly less than n. There is a parameter *bchar*, which is either 256 or an implicit right boundary character assumed to be present just following x_n. (The value $hu[n+1]$ is never explicitly examined, but the algorithm imagines that *bchar* is there.)

If there exists an index k in the range $j \leq k \leq m$ such that $hyf[k]$ is odd and such that the result of *reconstitute* would have been different if x_{k+1} had been *hchar*, then *reconstitute* sets *hyphen_passed* to the smallest such k. Otherwise it sets *hyphen_passed* to zero.

A special convention is used in the case $j \equiv 0$: Then we assume that the translation of $hu[0]$ appears in a special list of charnodes starting at *init_list*; moreover, if *init_lig* is *true*, then $hu[0]$ will be a ligature character, involving a left boundary if *init_lft* is *true*. This facility is provided for cases when a hyphenated word is preceded by punctuation (like single or double quotes) that might affect the translation of the beginning of the word.

      nonempty 910 ⟩;
    return j;
  }

This code is used in section 895.

907.   The reconstitution procedure shares many of the global data structures by which TEX has processed the words before they were hyphenated. There is an implied "cursor" between characters cur_l and cur_r; these characters will be tested for possible ligature activity. If $ligature\_present$ then cur_l is a ligature character formed from the original characters following cur_q in the current translation list. There is a "ligature stack" between the cursor and character $j + 1$, consisting of pseudo-ligature nodes linked together by their $link$ fields. This stack is normally empty unless a ligature command has created a new character that will need to be processed later. A pseudo-ligature is a special node having a *character* field that represents a potential ligature and a lig_ptr field that points to a $char\_node$ or is $null$. We have

$$cur\_r = \begin{cases} character(lig\_stack), & \text{if } lig\_stack > null; \\ qi(hu[j+1]), & \text{if } lig\_stack \equiv null \text{ and } j < n; \\ bchar, & \text{if } lig\_stack \equiv null \text{ and } j \equiv n. \end{cases}$$

This code is used in section 909.

912.   Okay, we're ready to insert the potential hyphenations that were found. When the following program is executed, we want to append the word $hu[1 .. hn]$ after node ha, and node q should be appended to the result. During this process, the variable i will be a temporary index into hu; the variable j will be an index to our current position in hu; the variable l will be the counterpart of j, in a discretionary branch; the variable r will point to new nodes being created; and we need a few new local variables:

⟨ Local variables for hyphenation 901 ⟩ +≡
   pointer $major\_tail$, $minor\_tail$;
     ▷ the end of lists in the main and discretionary branches being reconstructed ◁
   ASCII_code c;   ▷ character temporarily replaced by a hyphen ◁
   int c_loc;   ▷ where that character came from ◁
   int r_count;   ▷ replacement count for discretionary ◁
   pointer hyf_node;   ▷ the hyphen, if it exists ◁

913.   When the following code is performed, $hyf[0]$ and $hyf[hn]$ will be zero.

⟨ Reconstitute nodes for the hyphenated word, inserting discretionary hyphens 913 ⟩ ≡
   do {
     $l \leftarrow j$; $j \leftarrow reconstitute(j, hn, bchar, qi(hyf\_char)) + 1$;
     if $(hyphen\_passed \equiv 0)$ { $link(s) \leftarrow link(hold\_head)$;
       while $(link(s) > null)$ $s \leftarrow link(s)$;
       if $(odd(hyf[j-1]))$ { $l \leftarrow j$; $hyphen\_passed \leftarrow j - 1$; $link(hold\_head) \leftarrow null$;
       }
     }
     if $(hyphen\_passed > 0)$
      ⟨ Create and append a discretionary node as an alternative to the unhyphenated word, and continue
         to develop both branches until they become equivalent 914 ⟩
   } **while** $(\neg(j > hn))$;
   $link(s) \leftarrow q$
This code is used in section 903.

914.   In this repeat loop we will insert another discretionary if $hyf[j-1]$ is odd, when both branches of the previous discretionary end at position $j-1$. Strictly speaking, we aren't justified in doing this, because we don't know that a hyphen after $j-1$ is truly independent of those branches. But in almost all applications we would rather not lose a potentially valuable hyphenation point. (Consider the word 'difficult', where the letter 'c' is in position j.)

#**define** $advance\_major\_tail$
     { $major\_tail \leftarrow link(major\_tail)$; $incr(r\_count)$;
     }

⟨ Create and append a discretionary node as an alternative to the unhyphenated word, and continue to
    develop both branches until they become equivalent 914 ⟩ ≡
   do {
     $r \leftarrow get\_node(small\_node\_size)$; $link(r) \leftarrow link(hold\_head)$; $type(r) \leftarrow disc\_node$; $major\_tail \leftarrow r$;
     $r\_count \leftarrow 0$;
     while $(link(major\_tail) > null)$ $advance\_major\_tail$;
     $i \leftarrow hyphen\_passed$; $hyf[i] \leftarrow 0$; ⟨ Put the characters $hu[l .. i]$ and a hyphen into $pre\_break(r)$ 915 ⟩;
     ⟨ Put the characters $hu[i+1..]$ into $post\_break(r)$, appending to this list and to $major\_tail$ until
        synchronization has been achieved 916 ⟩;
     ⟨ Move pointer s to the end of the current list, and set $replace\_count(r)$ appropriately 918 ⟩;
     $hyphen\_passed \leftarrow j - 1$; $link(hold\_head) \leftarrow null$;
   } **while** $(\neg(\neg odd(hyf[j-1])))$;
This code is used in section 913.

915. The new hyphen might combine with the previous character via ligature or kern. At this point we
have $l - 1 \leq i < j$ and $i < hn$.

⟨Put the characters $hu[l .. i]$ and a hyphen into $pre\_break(r)$ 915 ⟩ ≡
  $minor\_tail \leftarrow null$; $pre\_break(r) \leftarrow null$; $hyf\_node \leftarrow new\_character(hf, hyf\_char)$;
  if $(hyf\_node \neq null)$ { $incr(i)$; $c \leftarrow hu[i]$; $hu[i] \leftarrow hyf\_char$; $free\_avail(hyf\_node)$;
  }
  while $(l \leq i)$ { $l \leftarrow reconstitute(l, i, font\_bchar[hf], non\_char) + 1$;
    if $(link(hold\_head) > null)$ { **if** $(minor\_tail \equiv null)$ $pre\_break(r) \leftarrow link(hold\_head)$;
      else $link(minor\_tail) \leftarrow link(hold\_head)$;
      $minor\_tail \leftarrow link(hold\_head)$;
      while $(link(minor\_tail) > null)$ $minor\_tail \leftarrow link(minor\_tail)$;
    }
  }
  if $(hyf\_node \neq null)$ { $hu[i] \leftarrow c$;   ▷ restore the character in the hyphen position ◁
    $l \leftarrow i$; $decr(i)$;
  }

This code is used in section 914.

916. The synchronization algorithm begins with $l \equiv i + 1 \leq j$.

⟨Put the characters $hu[i + 1..]$ into $post\_break(r)$, appending to this list and to $major\_tail$ until
      synchronization has been achieved 916 ⟩ ≡
  $minor\_tail \leftarrow null$; $post\_break(r) \leftarrow null$; $c\_loc \leftarrow 0$;
  if $(bchar\_label[hf] \neq non\_address)$ ▷ put left boundary at beginning of new line ◁
  { $decr(l)$; $c \leftarrow hu[l]$; $c\_loc \leftarrow l$; $hu[l] \leftarrow 256$;
  }
  while $(l < j)$ { **do** {
      $l \leftarrow reconstitute(l, hn, bchar, non\_char) + 1$;
      if $(c\_loc > 0)$ { $hu[c\_loc] \leftarrow c$; $c\_loc \leftarrow 0$;
      }
      if $(link(hold\_head) > null)$ { **if** $(minor\_tail \equiv null)$ $post\_break(r) \leftarrow link(hold\_head)$;
        else $link(minor\_tail) \leftarrow link(hold\_head)$;
        $minor\_tail \leftarrow link(hold\_head)$;
        while $(link(minor\_tail) > null)$ $minor\_tail \leftarrow link(minor\_tail)$;
      }
    } **while** $(\neg(l \geq j))$;
    while $(l > j)$ ⟨Append characters of hu [j ..] to $major\_tail$, advancing j 917 ⟩;
  }

This code is used in section 914.

917. ⟨Append characters of hu [j ..] to $major\_tail$, advancing j 917 ⟩ ≡
  { $j \leftarrow reconstitute(j, hn, bchar, non\_char) + 1$; $link(major\_tail) \leftarrow link(hold\_head)$;
    while $(link(major\_tail) > null)$ $advance\_major\_tail$;
  }

This code is used in section 916.

918. Ligature insertion can cause a word to grow exponentially in size. Therefore we must test the size of r_count here, even though the hyphenated text was at most 63 characters long.

$\langle$ Move pointer s to the end of the current list, and set $replace\_count(r)$ appropriately 918 $\rangle \equiv$
    if $(r\_count > 127)$ $\triangleright$ we have to forget the discretionary hyphen $\triangleleft$
    $\{$ $link(s) \leftarrow link(r)$; $link(r) \leftarrow null$; $flush\_node\_list(r)$;
    $\}$
    else $\{$ $link(s) \leftarrow r$; $set\_replace\_count(r, r\_count)$; $set\_auto\_disc(r)$;
    $\}$
    $s \leftarrow major\_tail$

This code is used in section 914.

919. Hyphenation. When a word $hc[1 .. hn]$ has been set up to contain a candidate for hyphenation, TeX first looks to see if it is in the user's exception dictionary. If not, hyphens are inserted based on patterns that appear within the given word, using an algorithm due to Frank M. Liang.

Let's consider Liang's method first, since it is much more interesting than the exception-lookup routine. The algorithm begins by setting $hyf[j]$ to zero for all j, and invalid characters are inserted into $hc[0]$ and $hc[hn+1]$ to serve as delimiters. Then a reasonably fast method is used to see which of a given set of patterns occurs in the word $hc[0 .. (hn+1)]$. Each pattern $p_1 \ldots p_k$ of length k has an associated sequence of $k+1$ numbers $n_0 \ldots n_k$; and if the pattern occurs in $hc[(j+1) .. (j+k)]$, TeX will set $hyf[j+i] \leftarrow \max(hyf[j+i], n\_i)$ for $0 \leq i \leq k$. After this has been done for each pattern that occurs, a discretionary hyphen will be inserted between $hc[j]$ and $hc[j+1]$ when $hyf[j]$ is odd, as we have already seen.

The set of patterns $p_1 \ldots p_k$ and associated numbers $n_0 \ldots n_k$ depends, of course, on the language whose words are being hyphenated, and on the degree of hyphenation that is desired. A method for finding appropriate p's and n's, from a given dictionary of words and acceptable hyphenations, is discussed in Liang's Ph.D. thesis (Stanford University, 1983); TeX simply starts with the patterns and works from there.

920. The patterns are stored in a compact table that is also efficient for retrieval, using a variant of "trie memory" [cf. *The Art of Computer Programming* **3** (1973), 481–505]. We can find each pattern $p_1 \ldots p_k$ by letting z_0 be one greater than the relevant language index and then, for $1 \leq i \leq k$, setting $z\_i \leftarrow trie\_link(z\_i-1)+p\_i$; the pattern will be identified by the number z_k. Since all the pattern information is packed together into a single *trie_link* array, it is necessary to prevent confusion between the data from inequivalent patterns, so another table is provided such that $trie\_char(z\_i)=p\_i$ for all i. There is also a table $trie\_op(z_k)$ to identify the numbers $n_0 \ldots n_k$ associated with $p_1 \ldots p_k$.

Comparatively few different number sequences $n_0 \ldots n_k$ actually occur, since most of the n's are generally zero. Therefore the number sequences are encoded in such a way that $trie\_op(z_k)$ is only one byte long. If $trie\_op(z\_k) \neq min\_quarterword$, when $p_1 \ldots p_k$ has matched the letters in $hc[(l-k+1) .. l]$ of language t, we perform all of the required operations for this pattern by carrying out the following little program: Set $v \leftarrow trie\_op(z\_k)$. Then set $v \leftarrow v + op\_start[t]$, $hyf[l - hyf\_distance[v]] \leftarrow \max(hyf[l - hyf\_distance[v]], hyf\_num[v])$, and $v \leftarrow hyf\_next[v]$; repeat, if necessary, until $v \equiv min\_quarterword$.

⟨Types in the outer block 18⟩ +≡
    typedef int32_t trie_pointer;   ▷ an index into *trie* ◁

921. **#define** $trie\_link(A)$ $trie[A].rh$ ▷ "downward" link in a trie ◁

      $v \leftarrow hyf\_next[v];$

    $\}$ **while** $(\neg(v \equiv min\_quarterword));$

  }

This code is used in section 923.

925.   The exception table that is built by TEX's \hyphenation primitive is organized as an ordered hash table [cf. Amble and Knuth, *The Computer Journal* **17** (1974), 135–142] using linear probing. If α and β are words, we will say that $\alpha < \beta$ if $|\alpha| < |\beta|$ or if $|\alpha| = |\beta|$ and α is lexicographically smaller than β. (The notation $|\alpha|$ stands for the length of α.) The idea of ordered hashing is to arrange the table so that a given word α can be sought by computing a hash address $h = h(\alpha)$ and then looking in table positions h, $h - 1$, ..., until encountering the first word $\leq \alpha$. If this word is different from α, we can conclude that α is not in the table.

  The words in the table point to lists in *mem* that specify hyphen positions in their *info* fields. The list for $c_1 \ldots c_n$ contains the number k if the word $c_1 \ldots c_n$ has a discretionary hyphen between c_k and c_{k+1}.

⟨Types in the outer block 18⟩ +≡

  typedef int16_t hyph_pointer;   ▷ an index into the ordered hash table ◁

926.   ⟨Global variables 13⟩ +≡

942.   Initializing the hyphenation tables.   The trie for TeX's hyphenation algorithm is built from a
sequence of patterns following a `\patterns` specification. Such a specification is allowed only in `INITEX`,
since the extra memory for auxiliary tables and for the initialization program itself would only clutter up
the production version of TeX with a lot of deadwood.

The first step is to build a trie that is linked, instead of packed into sequential storage, so that insertions
are readily made. After all patterns have been processed, `INITEX` compresses the linked trie by identifying
common subtries. Finally the trie is packed into the efficient sequential form that the hyphenation algorithm
actually uses.

⟨ Declare subprocedures for *line_break* 826 ⟩ +≡
#ifdef INIT
  ⟨ Declare procedures for preprocessing hyphenation patterns 944 ⟩
#endif

943.   Before we discuss trie building in detail, let's consider the simpler problem of creating the
hyf_distance, *hyf_num*, and *hyf_next* arrays.

Suppose, for example, that TeX reads the pattern 'ab2cde1'. This is a pattern of length 5, with $n_0 \ldots n_5 = 0\,0\,2\,0\,0\,1$ in the notation above. We want the corresponding *trie_op* code v to have $hyf\_distance[v] \equiv 3$,
$hyf\_num[v] \equiv 2$, and $hyf\_next[v] \equiv v'$, where the auxiliary *trie_op* code v' has $hyf\_distance[v'] \equiv 0$,
$hyf\_num[v'] \equiv 1$, and $hyf\_next[v'] \equiv min\_quarterword$.

TeX computes an appropriate value v with the *new_trie_op* subroutine below, by setting

$$v' \leftarrow new\_trie\_op(0, 1, min\_quarterword), \qquad v \leftarrow new\_trie\_op(3, 2, v').$$

This subroutine looks up its three parameters in a special hash table, assigning a new value only if these
three have not appeared before for the current language.

The hash table is called *trie_op_hash*, and the number of entries it contains is *trie_op_ptr*.

⟨ Global variables 13 ⟩ +≡
#ifdef INIT
  static uint16_t *trie_op_hash0*[*trie_op_size* + *trie_op_size* + 1],
       *const *trie_op_hash* ← *trie_op_hash0* + *trie_op_size*;   ▷ trie op codes for quadruples ◁
  static quarterword *trie_used*[256];   ▷ largest opcode used so far for this language ◁
  static ASCII_code *trie_op_lang0*[*trie_op_size*], ***const** *trie_op_lang* ← *trie_op_lang0* − 1;
     ▷ language part of a hashed quadruple ◁
  static quarterword *trie_op_val0*[*trie_op_size*], ***const** *trie_op_val* ← *trie_op_val0* − 1;
     ▷ opcode corresponding to a hashed quadruple ◁
  static int *trie_op_ptr*;   ▷ number of stored ops so far ◁
#endif

944. It's tempting to remove the *overflow* stops in the following procedure; *new_trie_op* could return *min_quarterword* (thereby simply ignoring part of a hyphenation pattern) instead of aborting the job. However, that would lead to different hyphenation results on different installations of TEX using the same patterns. The *overflow* stops are necessary for portability of patterns.

⟨Declare procedures for preprocessing hyphenation patterns 944⟩ ≡
  static quarterword *new_trie_op*(**small_number** d, **small_number** n, **quarterword** v)
  { **int** h;   ▷ trial hash location ◁

    }
  }

See also sections 948, 949, 953, 957, 959, 960, and 966.

This code is used in section 942.

945. After *new_trie_op* has compressed the necessary opcode information, plenty of information is available to unscramble the data into the final form needed by our hyphenation algorithm.

⟨Sort the hyphenation op tables into proper order 945⟩ ≡
  $op\_start[0] \leftarrow -min\_quarterword$;
  for $(j \leftarrow 1;\ j \leq 255;\ j{+}{+})$ $op\_start[j] \leftarrow op\_start[j-1] + qo(trie\_used[j-1])$;
  for $(j \leftarrow 1;\ j \leq trie\_op\_ptr;\ j{+}{+})$ $trie\_op\_hash[j] \leftarrow op\_start[trie\_op\_lang[j]] + trie\_op\_val[j]$;
    ▷ destination ◁
  for $(j \leftarrow 1;\ j \leq trie\_op\_ptr;\ j{+}{+})$
    while $(trie\_op\_hash[j] > j)$ { $k \leftarrow trie\_op\_hash[j]$;
      $t \leftarrow hyf\_distance[k]$; $hyf\_distance[k] \leftarrow hyf\_distance[j]$; $hyf\_distance[j] \leftarrow t$;
      $t \leftarrow hyf\_num[k]$; $hyf\_num[k] \leftarrow hyf\_num[j]$; $hyf\_num[j] \leftarrow t$;
      $t \leftarrow hyf\_next[k]$; $hyf\_next[k] \leftarrow hyf\_next[j]$; $hyf\_next[j] \leftarrow t$;
      $trie\_op\_hash[j] \leftarrow trie\_op\_hash[k]$; $trie\_op\_hash[k] \leftarrow k$;
    }

This code is used in section 952.

946. Before we forget how to initialize the data structures that have been mentioned so far, let's write down the code that gets them started.

⟨Initialize table entries (done by `INITEX` only) 164⟩ +≡
  for $(k \leftarrow -trie\_op\_size;\ k \leq trie\_op\_size;\ k{+}{+})$ $trie\_op\_hash[k] \leftarrow 0$;
  for $(k \leftarrow 0;\ k \leq 255;\ k{+}{+})$ $trie\_used[k] \leftarrow min\_quarterword$;
  $trie\_op\_ptr \leftarrow 0$;

947.   The linked trie that is used to preprocess hyphenation patterns appears in several global arrays. Each
node represents an instruction of the form "if you see character c, then perform operation o, move to the
next character, and go to node l; otherwise go to node r." The four quantities c, o, l, and r are stored in
four arrays $trie\_c$, $trie\_o$, $trie\_l$, and $trie\_r$. The root of the trie is $trie\_l[0]$, and the number of nodes is
$trie\_ptr$. Null trie pointers are represented by zero. To initialize the trie, we simply set $trie\_l[0]$ and $trie\_ptr$
to zero. We also set $trie\_c[0]$ to some arbitrary value, since the algorithm may access it.

The algorithms maintain the condition

$$trie\_c[trie\_r[z]] > trie\_c[z] \qquad \text{whenever } z \neq 0 \text{ and } trie\_r[z] \neq 0;$$

in other words, sibling nodes are ordered by their c fields.

#**define** $trie\_root$ $trie\_l[0]$ ▷ root of the linked trie ◁

⟨ Global variables 13 ⟩ +≡
#**ifdef** INIT
  static packed_ASCII_code $trie\_c[trie\_size + 1]$;   ▷ characters to match ◁
    static quarterword $trie\_o[trie\_size + 1]$;   ▷ operations to perform ◁
    static trie_pointer $trie\_l[trie\_size + 1]$;   ▷ left subtrie links ◁
    static trie_pointer $trie\_r[trie\_size + 1]$;   ▷ right subtrie links ◁
    static trie_pointer $trie\_ptr$;   ▷ the number of nodes in the trie ◁
    static trie_pointer $trie\_hash[trie\_size + 1]$;   ▷ used to identify equivalent subtries ◁
#**endif**

948.   Let us suppose that a linked trie has already been constructed. Experience shows that we can often
reduce its size by recognizing common subtries; therefore another hash table is introduced for this purpose,
somewhat similar to $trie\_op\_hash$. The new hash table will be initialized to zero.

The function $trie\_node(p)$ returns p if p is distinct from other nodes that it has seen, otherwise it returns
the number of the first equivalent node that it has seen.

Notice that we might make subtries equivalent even if they correspond to patterns for different languages,
in which the trie ops might mean quite different things. That's perfectly all right.

⟨ Declare procedures for preprocessing hyphenation patterns 944 ⟩ +≡
  static trie_pointer $trie\_node(\textbf{trie\_pointer } p)$ ▷ converts to a canonical form ◁
  { **trie_pointer** h;   ▷ trial hash location ◁
    trie_pointer q;   ▷ trial trie node ◁

    $h \leftarrow abs(trie\_c[p] + 1009 * trie\_o[p] + 2718 * trie\_l[p] + 3142 * trie\_r[p]) \% trie\_size$;
    loop { $q \leftarrow trie\_hash[h]$;
      if $(q \equiv 0)$ { $trie\_hash[h] \leftarrow p$; **return** p;
      }
      if $((trie\_c[q] \equiv trie\_c[p]) \wedge (trie\_o[q] \equiv trie\_o[p]) \wedge (trie\_l[q] \equiv trie\_l[p]) \wedge (trie\_r[q] \equiv trie\_r[p]))$ {
        return q;
      }
      if $(h > 0)$ $decr(h)$; **else** $h \leftarrow trie\_size$;
    }
  }

949.   A neat recursive procedure is now able to compress a trie by traversing it and applying *trie_node* to its nodes in "bottom up" fashion. We will compress the entire trie by clearing *trie_hash* to zero and then saying '*trie_root* ← *compress_trie*(*trie_root*)'.

⟨ Declare procedures for preprocessing hyphenation patterns 944 ⟩ +≡
  static trie_pointer *compress_trie*(**trie_pointer** *p*)
  { **if** (*p* ≡ 0) **return** 0;
    else { *trie_l*[*p*] ← *compress_trie*(*trie_l*[*p*]); *trie_r*[*p*] ← *compress_trie*(*trie_r*[*p*]);
      return *trie_node*(*p*);
    }
  }

950.   The compressed trie will be packed into the *trie* array using a "top-down first-fit" procedure. This is a little tricky, so the reader should pay close attention: The *trie_hash* array is cleared to zero again and renamed *trie_ref* for this phase of the operation; later on, *trie_ref*[*p*] will be nonzero only if the linked trie node *p* is the smallest character in a family and if the characters *c* of that family have been allocated to locations *trie_ref*[*p*] + *c* in the *trie* array. Locations of *trie* that are in use will have *trie_link* ≡ 0, while the unused holes in *trie* will be doubly linked with *trie_link* pointing to the next larger vacant location and *trie_back* pointing to the next smaller one. This double linking will have been carried out only as far as *trie_max*, where *trie_max* is the largest index of *trie* that will be needed. To save time at the low end of the trie, we maintain array entries *trie_min*[*c*] pointing to the smallest hole that is greater than *c*. Another array *trie_taken* tells whether or not a given location is equal to *trie_ref*[*p*] for some *p*; this array is used to ensure that distinct nodes in the compressed trie will have distinct *trie_ref* entries.

\#**define** *trie_ref*   *trie_hash*   ▷ where linked trie families go into *trie* ◁
\#**define** *trie_back*(*A*)   *trie*[*A*].*lh*   ▷ backward links in *trie* holes ◁

⟨ Global variables 13 ⟩ +≡
\#**ifdef** INIT

    ▷ identify equivalent subtries ◁
  for (*p* ← 0; *p* ≤ *trie_ptr*; *p*++) *trie_ref*[*p*] ← 0;
  for (*p* ← 0; *p* ≤ 255; *p*++) *trie_min*[*p*] ← *p* + 1;
  trie_link(0) ← 1; *trie_max* ← 0

This code is used in section 966.

953.   The *first_fit* procedure finds the smallest hole z in *trie* such that a trie family starting at a given node p will fit into vacant positions starting at z. If $c \equiv trie\_c[p]$, this means that location $z - c$ must not already be taken by some other family, and that $z - c + c'$ must be vacant for all characters c' in the family. The procedure sets *trie_ref*[p] to $z - c$ when the first fit has been found.

⟨ Declare procedures for preprocessing hyphenation patterns 944 ⟩ +≡
   static void *first_fit*(**trie_pointer** p)   ▷ packs a family into *trie* ◁
  { **trie_pointer** h;   ▷ candidate for *trie_ref*[p] ◁
    trie_pointer z;   ▷ runs through holes ◁
    trie_pointer q;   ▷ runs through the family starting at p ◁
    ASCII_code c;   ▷ smallest character in the family ◁
    trie_pointer l, r;   ▷ left and right neighbors ◁
    int ll;   ▷ upper limit of *trie_min* updating ◁

    $c \leftarrow so(trie\_c[p]);\ z \leftarrow trie\_min[c];$ ▷ get the first conceivably good hole ◁
    loop { $h \leftarrow z - c$;
      ⟨ Ensure that $trie\_max \geq h + 256$ 954 ⟩;
      if ($trie\_taken[h]$) **goto** *not_found*;
      ⟨ If all characters of the family fit relative to h, then **goto** *found*, otherwise **goto** *not_found* 955 ⟩;
      not_found: $z \leftarrow trie\_link(z)$;   ▷ move to the next hole ◁
    }
  found: ⟨ Pack the family into *trie* relative to h 956 ⟩
  }

954.   By making sure that $trie\_max$ is at least $h + 256$, we can be sure that $trie\_max > z$, since $h \equiv z - c$. It follows that location $trie\_max$ will never be occupied in *trie*, and we will have $trie\_max \geq trie\_link(z)$.

⟨ Ensure that $trie\_max \geq h + 256$ 954 ⟩ ≡
  if ($trie\_max < h + 256$) { **if** ($trie\_size \leq h + 256$) *overflow*("pattern␣memory", $trie\_size$);
    do {
      $incr(trie\_max);\ trie\_taken[trie\_max] \leftarrow false;\ trie\_link(trie\_max) \leftarrow trie\_max + 1;$
      $trie\_back(trie\_max) \leftarrow trie\_max - 1;$
    } **while** ($\neg(trie\_max \equiv h + 256)$);
  }

This code is used in section 953.

955.   ⟨ If all characters of the family fit relative to h, then **goto** *found*, otherwise **goto** *not_found* 955 ⟩ ≡
  $q \leftarrow trie\_r[p]$;
  while ($q > 0$) { **if** ($trie\_link(h + so(trie\_c[q])) \equiv 0$) **goto** *not_found*;
    $q \leftarrow trie\_r[q]$;
  }
  goto *found*

This code is used in section 953.

956.   ⟨Pack the family into *trie* relative to h 956⟩ ≡
  trie_taken[h] ← *true*; *trie_ref*[p] ← h; $q ← p$;
  do {
    $z ← h + so(trie\_c[q])$; $l ← trie\_back(z)$; $r ← trie\_link(z)$; $trie\_back(r) ← l$; $trie\_link(l) ← r$;
    trie_link(z) ← 0;
    if ($l < 256$) { **if** ($z < 256$) $ll ← z$; **else** $ll ← 256$;
      do {
        trie_min[l] ← r; *incr*(l);
      } **while** ($¬(l ≡ ll)$);
    }
    $q ← trie\_r[q]$;
  } **while** ($¬(q ≡ 0)$);
This code is used in section 953.

957.   To pack the entire linked trie, we use the following recursive procedure.

⟨Declare procedures for preprocessing hyphenation patterns 944⟩ +≡
  static void *trie_pack*(**trie_pointer** p)   ▷ pack subtries of a family ◁
  { **trie_pointer** q;   ▷ a local variable that need not be saved on recursive calls ◁
    do {
      $q ← trie\_l[p]$;
      if (($q > 0$) ∧ (*trie_ref*[q] ≡ 0)) { *first_fit*(q); *trie_pack*(q);
      }
      $p ← trie\_r[p]$;
    } **while** ($¬(p ≡ 0)$);
  }

958.   When the whole trie has been allocated into the sequential table, we must go through it once again so that *trie* contains the correct information. Null pointers in the linked trie will be represented by the value 0, which properly implements an "empty" family.

⟨Move the data into *trie* 958⟩ ≡
  $h.rh ← 0$; $h.b0 ← min\_quarterword$; $h.b1 ← min\_quarterword$;
    ▷ *trie_link* ← 0, *trie_op* ← *min_quarterword*, *trie_char* ← $qi(0)$ ◁
  if (*trie_max* ≡ 0)   ▷ no patterns were given ◁
  { **for** ($r ← 0$; $r ≤ 256$; r++) *trie*[r] ← h;
    trie_max ← 256;
  }
  else { **if** (*hyph_root* > 0) *trie_fix*(*hyph_root*);
    if (*trie_root* > 0) *trie_fix*(*trie_root*);   ▷ this fixes the non-holes in *trie* ◁
    $r ← 0$;   ▷ now we will zero out all the holes ◁
    do {
      $s ← trie\_link(r)$; *trie*[r] ← h; $r ← s$;
    } **while** ($¬(r > trie\_max)$);
  }
  trie_char(0) ← $qi(?)$;   ▷ make *trie_char*(c) ≠ c for all c ◁
This code is used in section 966.

959. The fixing-up procedure is, of course, recursive. Since the linked trie usually has overlapping subtries, the same data may be moved several times; but that causes no harm, and at most as much work is done as it took to build the uncompressed trie.

⟨ Declare procedures for preprocessing hyphenation patterns 944 ⟩ +≡

   static void *trie_fix*(**trie_pointer** p)   ▷ moves p and its siblings into *trie* ◁

  { **trie_pointer** q;   ▷ a local variable that need not be saved on recursive calls ◁

    ASCII_code c;   ▷ another one that need not be saved ◁

    trie_pointer z;   ▷ *trie* reference; this local variable must be saved ◁

    $z \leftarrow trie\_ref[p]$;

    do {

      $q \leftarrow trie\_l[p]$; $c \leftarrow so(trie\_c[p])$; $trie\_link(z + c) \leftarrow trie\_ref[q]$; $trie\_char(z + c) \leftarrow qi(c)$;

      $trie\_op(z + c) \leftarrow trie\_o[p]$;

      if $(q > 0)$ $trie\_fix(q)$;

      $p \leftarrow trie\_r[p]$;

    } **while** $(\neg(p \equiv 0))$;

  }

960. Now let's go back to the easier problem, of building the linked trie. When INITEX has scanned the '\patterns' control sequence, it calls on *new_patterns* to do the right thing.

⟨ Declare procedures for preprocessing hyphenation patterns 944 ⟩ +≡

   static void *new_patterns*(**void**)   ▷ initializes the hyphenation pattern data ◁

  { **int** k, l;   ▷ indices into *hc* and *hyf*; not always in **small_number** range ◁

    bool *digit_sensed*;   ▷ should the next digit be treated as a letter? ◁

    quarterword v;   ▷ trie op code ◁

    trie_pointer p, q;   ▷ nodes of trie traversed during insertion ◁

    bool *first_child*;   ▷ is $p \equiv trie\_l[q]$? ◁

    int c;   ▷ character being inserted ◁

    if $(trie\_not\_ready)$ { set_cur_lang; $scan\_left\_brace(\,)$;   ▷ a left brace must follow \patterns ◁

      ⟨ Enter all of the patterns into a linked trie, until coming to a right brace 961 ⟩;

      if $(saving\_hyph\_codes > 0)$ ⟨ Store hyphenation codes for current language 1527 ⟩;

    }

    else { $print\_err("Too\_late\_for\_")$; $print\_esc("patterns")$;

      $help1("All\_patterns\_must\_be\_given\_before\_typesetting\_begins.")$; $error(\,)$;

      $link(garbage) \leftarrow scan\_toks(false, false)$; $flush\_list(def\_ref)$;

    }

  }

961.   Novices are not supposed to be using \patterns, so the error messages are terse. (Note that all error messages appear in TEX's string pool, even if they are used only by INITEX.)

⟨ Enter all of the patterns into a linked trie, until coming to a right brace 961 ⟩ ≡
    $k \leftarrow 0$; $hyf[0] \leftarrow 0$; $digit\_sensed \leftarrow false$;
    loop { $get\_x\_token(\,)$;
        switch (cur_cmd) {
        case $letter$: **case** $other\_char$: ⟨ Append a new letter or a hyphen level 962 ⟩ **break**;
        case $spacer$: **case** $right\_brace$:
            { **if** ($k > 0$) ⟨ Insert a new pattern into the linked trie 963 ⟩;
                if ($cur\_cmd \equiv right\_brace$) **goto** $done$;
                $k \leftarrow 0$; $hyf[0] \leftarrow 0$; $digit\_sensed \leftarrow false$;
            } **break**;
        default:
            { $print\_err("Bad␣")$; $print\_esc("patterns")$; $help1("(See␣Appendix␣H.)")$; $error(\,)$;
            }
        }
    }
    $done$:
This code is used in section 960.

962.   ⟨ Append a new letter or a hyphen level 962 ⟩ ≡
    if ($digit\_sensed \vee (cur\_chr < \text{'0'}) \vee (cur\_chr > \text{'9'})$) { **if** ($cur\_chr \equiv \text{'.'}$) $cur\_chr \leftarrow 0$;
            ▷ edge-of-word delimiter ◁
        else { $cur\_chr \leftarrow lc\_code(cur\_chr)$;
            if ($cur\_chr \equiv 0$) { $print\_err("Nonletter")$; $help1("(See␣Appendix␣H.)")$; $error(\,)$;
            }
        }
        if ($k < 63$) { $incr(k)$; $hc[k] \leftarrow cur\_chr$; $hyf[k] \leftarrow 0$; $digit\_sensed \leftarrow false$;
        }
    }
    else if ($k < 63$) { $hyf[k] \leftarrow cur\_chr - \text{'0'}$; $digit\_sensed \leftarrow true$;
    }
This code is used in section 961.

963.   When the following code comes into play, the pattern $p_1 \ldots p_k$ appears in $hc[1 \mathrel{.\,.} k]$, and the corresponding sequence of numbers $n_0 \ldots n_k$ appears in $hyf[0 \mathrel{.\,.} k]$.

⟨Insert a new pattern into the linked trie 963⟩ ≡
  { ⟨Compute the trie op code, v, and set $l: \leftarrow 0$ 965⟩;
    $q \leftarrow 0$; $hc[0] \leftarrow cur\_lang$;

    if $(l > 0)$ $decr(l)$; **else goto** $done1$;
  }
  $done1$:

This code is used in section 963.

966.   Finally we put everything together: Here is how the trie gets to its final, efficient form. The following packing routine is rigged so that the root of the linked tree gets mapped into location 1 of *trie*, as required by the hyphenation algorithm. This happens because the first call of *first_fit* will "take" location 1.

⟨ Declare procedures for preprocessing hyphenation patterns 944 ⟩ +≡

  static void *init_trie*(**void**)

  { **int** *p*;   ▷ pointer for initialization ◁

    int *j, k, t*;   ▷ all-purpose registers for initialization ◁

    int *r, s*;   ▷ used to clean up the packed *trie* ◁

    two_halves *h*;   ▷ template used to zero out *trie*'s holes ◁

    ⟨ Get ready to compress the trie 952 ⟩;

    if (*trie_root* ≠ 0) { *first_fit*(*trie_root*); *trie_pack*(*trie_root*);

    }

    if (*hyph_root* ≠ 0) ⟨ Pack all stored *hyph_codes* 1529 ⟩;

    ⟨ Move the data into *trie* 958 ⟩;

    trie_not_ready ← *false*;

  }

967. Breaking vertical lists into pages. The *vsplit* procedure, which implements TeX's `\vsplit` operation, is considerably simpler than *line_break* because it doesn't have to worry about hyphenation, and because its mission is to discover a single break instead of an optimum sequence of breakpoints. But before we get into the details of *vsplit*, we need to consider a few more basic things.

968.   A subroutine called *prune_page_top* takes a pointer to a vlist and returns a pointer to a modified vlist in which all glue, kern, and penalty nodes have been deleted before the first box or rule node. However, the first box or rule is actually preceded by a newly created glue node designed so that the topmost baseline will be at distance *split_top_skip* from the top, whenever this is possible without backspacing.

When the second argument *s* is *false* the deleted nodes are destroyed, otherwise they are collected in a list starting at *split_disc*.

In this routine and those that follow, we make use of the fact that a vertical list contains no character nodes, hence the *type* field exists for each node in the list.

```
static pointer prune_page_top(pointer p, bool s)      ▷ adjust top after page break ◁
{ pointer prev_p;      ▷ lags one step behind p ◁
  pointer q, r;      ▷ temporary variables for list manipulation ◁

  prev_p ← temp_head; link(temp_head) ← p;
  while (p ≠ null)
    switch (type(p)) {
    case hlist_node: case vlist_node: case rule_node:
      ⟨ Insert glue for split_top_skip and set p: ← null 969 ⟩ break;
    case whatsit_node: case mark_node: case ins_node:
      { prev_p ← p; p ← link(prev_p);
      } break;
    case glue_node: case kern_node: case penalty_node:
      { q ← p; p ← link(q); link(q) ← null; link(prev_p) ← p;
        if (s) { if (split_disc ≡ null) split_disc ← q; else link(r) ← q;
          r ← q;
        }
        else flush_node_list(q);
      } break;
    default: confusion("pruning");
    }
  return link(temp_head);
}
```

969.   ⟨ Insert glue for *split_top_skip* and set p: ← *null* 969 ⟩ ≡
```
{ q ← new_skip_param(split_top_skip_code); link(prev_p) ← q; link(q) ← p;
    ▷ now temp_ptr ≡ glue_ptr(q) ◁
  if (width(temp_ptr) > height(p)) width(temp_ptr) ← width(temp_ptr) − height(p);
  else width(temp_ptr) ← 0;
  p ← null;
}
```
This code is used in section 968.

970.   The next subroutine finds the best place to break a given vertical list so as to obtain a box of height h, with maximum depth d. A pointer to the beginning of the vertical list is given, and a pointer to the optimum breakpoint is returned. The list is effectively followed by a forced break, i.e., a penalty node with the *eject_penalty*; if the best break occurs at this artificial node, the value *null* is returned.

An array of six **scaled** distances is used to keep track of the height from the beginning of the list to the current place, just as in *line_break*. In fact, we use one of the same arrays, only changing its name to reflect its new significance.

#**define** *active_height*   *active_width*   ▷ new name for the six distance variables ◁
#**define** *cur_height*   *active_height*[1]   ▷ the natural height ◁
#**define** *set_height_zero*(*A*)   *active_height*[*A*] ← 0   ▷ initialize the height to zero ◁

  static pointer *vert_break*(**pointer** *p*, **scaled** *h*, **scaled** *d*)   ▷ finds optimum page break ◁
  { **pointer** *prev_p*;   ▷ if *p* is a glue node, *type*(*prev_p*) determines whether *p* is a legal breakpoint ◁
    pointer *q*, *r*;   ▷ glue specifications ◁
    int *pi*;   ▷ penalty value ◁
    int *b*;   ▷ badness at a trial breakpoint ◁
    int *least_cost*;   ▷ the smallest badness plus penalties found so far ◁
    pointer *best_place*;   ▷ the most recent break that leads to *least_cost* ◁
    scaled *prev_dp*;   ▷ depth of previous box in the list ◁
    small_number *t*;   ▷ *type* of the node following a kern ◁

    prev_p ← *p*;   ▷ an initial glue node is not a legal breakpoint ◁
    least_cost ← *awful_bad*; *do_all_six*(*set_height_zero*); *prev_dp* ← 0;
    loop { ⟨ If node *p* is a legal breakpoint, check if this break is the best known, and **goto** *done* if *p* is

         "Such␣glue␣doesn't␣belong␣there;␣but␣you␣can␣safely␣proceed,",

         "since␣the␣offensive␣shrinkability␣has␣been␣made␣finite."); *error*( ); *r* ← *new_spec*(*q*);

         shrink_order(*r*) ← *normal*; *delete_glue_ref*(*q*); *glue_ptr*(*p*) ← *r*; *q* ← *r*;

       }

    }

    cur_height ← *cur_height* + *prev_dp* + *width*(*q*); *prev_dp* ← 0

This code is used in section 972.

977.   Now we are ready to consider *vsplit* itself. Most of its work is accomplished by the two subroutines that we have just considered.

    Given the number of a vlist box *n*, and given a desired page height *h*, the *vsplit* function finds the best initial segment of the vlist and returns a box for a page of height *h*. The remainder of the vlist, if any, replaces the original box, after removing glue and penalties and adjusting for *split_top_skip*. Mark nodes in the split-off box are used to set the values of *split_first_mark* and *split_bot_mark*; we use the fact that *split_first_mark* ≡ *null* if and only if *split_bot_mark* ≡ *null*.

    The original box becomes "void" if and only if it has been entirely extracted. The extracted box is "void" if and only if the original box was void (or if it was, erroneously, an hlist box).

⟨ Declare the function called *do_marks* 1509 ⟩

    static pointer *vsplit*(**halfword** *n*, **scaled** *h*)   ▷ extracts a page of height *h* from box *n* ◁

    { **pointer** *v*;   ▷ the box to be split ◁

      pointer *p*;   ▷ runs through the vlist ◁

      pointer *q*;   ▷ points to where the break occurs ◁

      cur_val ← *n*; *fetch_box*(*v*); *flush_node_list*(*split_disc*); *split_disc* ← *null*;

      if (*sa_mark* ≠ *null*)

        if (*do_marks*(*vsplit_init*, 0, *sa_mark*)) *sa_mark* ← *null*;

      if (*split_first_mark* ≠ *null*) { *delete_token_ref*(*split_first_mark*); *split_first_mark* ← *null*;

        delete_token_ref(*split_bot_mark*); *split_bot_mark* ← *null*;

      }

      ⟨ Dispense with trivial cases of void or bad boxes 978 ⟩;

      q ← *vert_break*(*list_ptr*(*v*), *h*, *split_max_depth*);

      ⟨ Look at all the marks in nodes before the break, and set the final link to *null* at the break 979 ⟩;

      q ← *prune_page_top*(*q*, *saving_vdiscards* > 0); *p* ← *list_ptr*(*v*); *list_ptr*(*v*) ← *null*; *flush_node_list*(*v*);

      if (*q* ≠ *null*) *q* ← *vpack*(*q*, *natural*);

      change_box(*q*);   ▷ the *eq_level* of the box stays the same ◁

      return *vpackage*(*p*, *h*, 0, 0, *exactly*, *split_max_depth*);

    }

978.   ⟨Dispense with trivial cases of void or bad boxes 978⟩ ≡
  if $(v \equiv null)$ { **return** $null$;
  }
  if $(type(v) \neq vlist\_node)$ { $print\_err("")$; $print\_esc("vsplit")$; $print("_{\sqcup}needs_{\sqcup}a_{\sqcup}")$;
    $print\_esc("vbox")$; $help2("The_{\sqcup}box_{\sqcup}you_{\sqcup}are_{\sqcup}trying_{\sqcup}to_{\sqcup}split_{\sqcup}is_{\sqcup}an_{\sqcup}\backslash\backslash hbox.",$

        }
        else { $delete\_token\_ref(split\_bot\_mark)$; $split\_bot\_mark \leftarrow mark\_ptr(p)$;
          $add\_token\_ref(split\_bot\_mark)$;
        }
      if $(link(p) \equiv q)$ { $link(p) \leftarrow null$; **goto** $done$;
      }
      $p \leftarrow link(p)$;
    }
  $done$:
This code is used in section 977.

980.   The page builder.   When TeX appends new material to its main vlist in vertical mode, it uses a method something like *vsplit* to decide where a page ends, except that the calculations are done "on line" as new items come in. The main complication in this process is that insertions must be put into their boxes and removed from the vlist, in a more-or-less optimum manner.

We shall use the term "current page" for that part of the main vlist that is being considered as a candidate for being broken off and sent to the user's output routine. The current page starts at $link(page\_head)$, and it ends at $page\_tail$. We have $page\_head \equiv page\_tail$ if this list is empty.

Utter chaos would reign if the user kept changing page specifications while a page is being constructed, so the page builder keeps the pertinent specifications frozen as soon as the page receives its first box or insertion. The global variable $page\_contents$ is $empty$ when the current page contains only mark nodes and content-less whatsit nodes; it is $inserts\_only$ if the page contains only insertion nodes in addition to marks and whatsits. Glue nodes, kern nodes, and penalty nodes are discarded until a box or rule node appears, at which time $page\_contents$ changes to box_there. As soon as $page\_contents$ becomes non-$empty$, the current $vsize$ and max_depth are squirreled away into $page\_goal$ and $page\_max\_depth$; the latter values will be used until the page has been forwarded to the user's output routine. The \topskip adjustment is made when $page\_contents$ changes to box_there.

Although $page\_goal$ starts out equal to $vsize$, it is decreased by the scaled natural height-plus-depth of the insertions considered so far, and by the \skip corrections for those insertions. Therefore it represents the size into which the non-inserted material should fit, assuming that all insertions in the current page have been made.

The global variables $best\_page\_break$ and $least\_page\_cost$ correspond respectively to the local variables $best\_place$ and $least\_cost$ in the $vert\_break$ routine that we have already studied; i.e., they record the location and value of the best place currently known for breaking the current page. The value of $page\_goal$ at the time of the best break is stored in $best\_size$.

#**define** $inserts\_only$ 1   ▷ $page\_contents$ when an insert node has been contributed, but no boxes ◁
#**define** box_there 2   ▷ $page\_contents$ when a box or rule has been contributed ◁

⟨ Global variables 13 ⟩ +≡
  static pointer $page\_tail$;   ▷ the final node on the current page ◁
  static int $page\_contents$;   ▷ what is on the current page so far? ◁
  static scaled $page\_max\_depth$;   ▷ maximum box depth on page being built ◁
  static pointer $best\_page\_break$;   ▷ break here to get the best page known so far ◁
  static int $least\_page\_cost$;   ▷ the score for this currently best page ◁
  static scaled $best\_size$;   ▷ its $page\_goal$ ◁

981. The page builder has another data structure to keep track of insertions. This is a list of four-word nodes, starting and ending at *page_ins_head*. That is, the first element of the list is node $r_1 \equiv$ *link*(*page_ins_head*); node r_j is followed by $r_j + 1 \equiv link(r_j)$; and if there are n items we have $r_n + 1 \equiv$ *page_ins_head*. The *subtype* field of each node in this list refers to an insertion number; for example, '\insert 250' would correspond to a node whose *subtype* is $qi(250)$ (the same as the *subtype* field of the relevant *ins_node*). These *subtype* fields are in increasing order, and $subtype(page\_ins\_head) \equiv qi(255)$, so *page_ins_head* serves as a convenient sentinel at the end of the list. A record is present for each insertion number that appears in the current page.

The *type* field in these nodes distinguishes two possibilities that might occur as we look ahead before deciding on the optimum page break. If $type(r) \equiv inserting$, then $height(r)$ contains the total of the height-plus-depth dimensions of the box and all its inserts seen so far. If $type(r) \equiv split\_up$, then no more insertions will be made into this box, because at least one previous insertion was too big to fit on the current page; $broken\_ptr(r)$ points to the node where that insertion will be split, if TeX decides to split it, $broken\_ins(r)$ points to the insertion node that was tentatively split, and $height(r)$ includes also the natural height plus depth of the part that would be split off.

In both cases, $last\_ins\_ptr(r)$ points to the last *ins_node* encountered for box $qo(subtype(r))$ that would be at least partially inserted on the next page; and $best\_ins\_ptr(r)$ points to the last such *ins_node* that should actually be inserted, to get the page with minimum badness among all page breaks considered so far. We have $best\_ins\_ptr(r) \equiv null$ if and only if no insertion for this box should be made to produce this optimum page.

The data structure definitions here use the fact that the *height* field appears in the fourth word of a box node.

#**define** *page_ins_node_size* 4   ▷ number of words for a page insertion node ◁
#**define** *inserting* 0   ▷ an insertion class that has not yet overflowed ◁
#**define** *split_up* 1   ▷ an overflowed insertion class ◁
#**define** *broken_ptr*(A) *link*(A + 1)   ▷ an insertion for this class will break here if anywhere ◁
#**define** *broken_ins*(A) *info*(A + 1)   ▷ this insertion might break at *broken_ptr* ◁
#**define** *last_ins_ptr*(A) *link*(A + 2)   ▷ the most recent insertion for this *subtype* ◁
#**define** *best_ins_ptr*(A) *info*(A + 2)   ▷ the optimum most recent insertion ◁

⟨Initialize the special list heads and constant nodes 790⟩ +≡
  $subtype(page\_ins\_head) \leftarrow qi(255);$ $type(page\_ins\_head) \leftarrow split\_up;$
  $link(page\_ins\_head) \leftarrow page\_ins\_head;$

982.   An array *page_so_far* records the heights and depths of everything on the current page. This array contains six **scaled** numbers, like the similar arrays already considered in *line_break* and *vert_break*; and it also contains *page_goal* and *page_depth*, since these values are all accessible to the user via *set_page_dimen* commands. The value of *page_so_far*[1] is also called *page_total*. The stretch and shrink components of the \skip corrections for each insertion are included in *page_so_far*, but the natural space components of these corrections are not, since they have been subtracted from *page_goal*.

The variable *page_depth* records the depth of the current page; it has been adjusted so that it is at most *page_max_depth*. The variable *last_glue* points to the glue specification of the most recent node contributed from the contribution list, if this was a glue node; otherwise *last_glue* ≡ *max_halfword*. (If the contribution list is nonempty, however, the value of *last_glue* is not necessarily accurate.) The variables *last_penalty*, *last_kern*, and *last_node_type* are similar. And finally, *insert_penalties* holds the sum of the penalties associated with all split and floating insertions.

#define *page_goal*   *page_so_far*[0]   ▷ desired height of information on page being built ◁

    print(",␣max␣depth="); *print_scaled*(*page_max_depth*); *end_diagnostic*(*false*);

  }

#**endif**

  }

988.   Pages are built by appending nodes to the current list in TEX's vertical mode, which is at the outermost level of the semantic nest. This vlist is split into two parts; the "current page" that we have been talking so much about already, and the "contribution list" that receives new nodes as they are created. The current page contains everything that the page builder has accounted for in its data structures, as described above, while the contribution list contains other things that have been generated by other parts of TEX but have not yet been seen by the page builder. The contribution list starts at *link*(*contrib_head*), and it ends at the current node in TEX's vertical mode.

  When TEX has appended new material in vertical mode, it calls the procedure *build_page*, which tries to catch up by moving nodes from the contribution list to the current page. This procedure will succeed in its goal of emptying the contribution list, unless a page break is discovered, i.e., unless the current page has grown to the point where the optimum next page break has been determined. In the latter case, the nodes after the optimum break will go back onto the contribution list, and control will effectively pass to the user's output routine.

  We make *type*(*page_head*) ≡ *glue_node*, so that an initial glue node on the current page will not be considered a valid breakpoint.

⟨ Initialize the special list heads and constant nodes 790 ⟩ +≡
  type(*page_head*) ← *glue_node*; *subtype*(*page_head*) ← *normal*;

989.   The global variable *output_active* is true during the time the user's output routine is driving TEX.

⟨ Global variables 13 ⟩ +≡
  static bool *output_active*;   ▷ are we in the midst of an output routine? ◁

990.   ⟨ Set initial values of key variables 21 ⟩ +≡
  output_active ← *false*; *insert_penalties* ← 0;

991.   The page builder is ready to start a fresh page if we initialize the following state variables. (However, the page insertion list is initialized elsewhere.)

⟨ Start a new current page 991 ⟩ ≡
  page_contents ← *empty*; *page_tail* ← *page_head*; *link*(*page_head*) ← *null*;
  last_glue ← *max_halfword*; *last_penalty* ← 0; *last_kern* ← 0; *last_node_type* ← −1;
  page_depth ← 0; *page_max_depth* ← 0
This code is used in sections 215 and 1017.

992.   At certain times box 255 is supposed to be void (i.e., *null*), or an insertion box is supposed to be ready to accept a vertical list. If not, an error message is printed, and the following subroutine flushes the unwanted contents, reporting them to the user.

  static void *box_error*(**eight_bits** *n*)
  { *error*(); *begin_diagnostic*(); *print_nl*("The␣following␣box␣has␣been␣deleted:");
    show_box(*box*(*n*)); *end_diagnostic*(*true*); *flush_node_list*(*box*(*n*)); *box*(*n*) ← *null*;
  }

993.   The following procedure guarantees that a given box register does not contain an `\hbox`.

> **static void** *ensure_vbox*(**eight_bits** *n*)
> { **pointer** *p*;   ▷ the box register contents ◁
>
>   *p* ← *box*(*n*);
>   **if** (*p* ≠ *null*)
>   **if** (*type*(*p*) ≡ *hlist_node*) { *print_err*("Insertions␣can␣only␣be␣added␣to␣a␣vbox");
>   *help3*("Tut␣tut:␣You're␣trying␣to␣\\insert␣into␣a",
>   "\\box␣register␣that␣now␣contains␣an␣\\hbox.",
>   "Proceed,␣and␣I'll␣discard␣its␣present␣contents."); *box_error*(*n*);
>   }
> }

994.   TEX is not always in vertical mode at the time *build_page* is called; the current mode reflects what TEX should return to, after the contribution list has been emptied. A call on *build_page* should be immediately followed by '**goto** *big_switch*', which is TEX's central control point.

> **static void** *update_last_values*(**pointer** *p*)
> {
>   ⟨Update the values of *last_glue*, *last_penalty*, and *last_kern* 996⟩;
> }

995.   #**define** *contrib_tail*   *nest*[0].*tail_field*   ▷ tail of the contribution list ◁

⟨Make the contribution list empty by setting its tail to *contrib_head* 995⟩ ≡
>   **if** (*nest_ptr* ≡ 0) *tail* ← *contrib_head*;   ▷ vertical mode ◁
>   **else** *contrib_tail* ← *contrib_head*   ▷ other modes ◁

This code is used in section 1712.

996.   ⟨Update the values of *last_glue*, *last_penalty*, and *last_kern* 996⟩ ≡
>   **if** (*last_glue* ≠ *max_halfword*) *delete_glue_ref*(*last_glue*);
>   *last_penalty* ← 0; *last_kern* ← 0; *last_node_type* ← *type*(*p*) + 1;
>   **if** (*type*(*p*) ≡ *glue_node*) { *last_glue* ← *glue_ptr*(*p*); *add_glue_ref*(*last_glue*);
>   }
>   **else** { *last_glue* ← *max_halfword*;
>   **if** (*type*(*p*) ≡ *penalty_node*) *last_penalty* ← *penalty*(*p*);
>   **else if** (*type*(*p*) ≡ *kern_node*) *last_kern* ← *width*(*p*);
>   }

This code is used in section 994.

997.   The code here is an example of a many-way switch into routines that merge together in different places. Some people call this unstructured programming, but the author doesn't see much wrong with it, as long as the various labels have a well-understood meaning.

⟨ Move node p to the current page; 997 ⟩ ≡
  ⟨ If the current page is empty and node p is to be deleted, **goto** *done1*; otherwise use node p to update the state of the current page; if this node is an insertion, **goto** *contribute*; otherwise if this node is not a legal breakpoint, **goto** *contribute* or *update_heights*; otherwise set *pi* to the penalty associated with this breakpoint 1000 ⟩;
  ⟨ Check if node p is a new champion breakpoint; then if it is time for a page break, prepare for output, and either fire up the user's output routine and **return** or ship out the page and **goto** *done* 1005 ⟩;
  if (($type(p) < glue\_node$) ∨ ($type(p) > kern\_node$)) **goto** *contribute*;
update_heights:
  ⟨ Update the current page measurements with respect to the glue or kern specified by node p 1004 ⟩;
contribute: ⟨ Make sure that *page_max_depth* is not exceeded 1003 ⟩;

      "since␣the␣offensive␣shrinkability␣has␣been␣made␣finite."$)$; $error(\,)$;
    }
  }

This code is used in section 1008.

1010.   Here is the code that will split a long footnote between pages, in an emergency. The current situation deserves to be recapitulated: Node p is an insertion into box n; the insertion will not fit, in its entirety, either because it would make the total contents of box n greater than \dimen n, or because it would make the incremental amount of growth h greater than the available space $delta$, or both. (This amount h has been weighted by the insertion scaling factor, i.e., by \count n over 1000.) Now we will choose the best way to break the vlist of the insertion, using the same criteria as in the \vsplit operation.

⟨ Find the best way to split the insertion, and change $type(r)$ to $split\_up$ 1010 ⟩ ≡

  { **if** $(count(n) \leq 0)$ $w \leftarrow max\_dimen$;

This code is used in section 1008.

1011.   ⟨Display the insertion split cost 1011⟩ ≡
{ *begin_diagnostic*( ); *print_nl*("%␣split"); *print_int*(*n*); *print*("␣to␣"); *print_scaled*(*w*);
  print_char(','); *print_scaled*(*best_height_plus_depth*);
  print("␣p=");
  if (*q* ≡ *null*) *print_int*(*eject_penalty*);
  else if (*type*(*q*) ≡ *penalty_node*) *print_int*(*penalty*(*q*));
  else *print_char*('0');
  end_diagnostic(*false*);
}

This code is used in section 1010.

1012.   When the page builder has looked at as much material as could appear before the next page break, it makes its decision. The break that gave minimum badness will be used to put a completed "page" into box 255, with insertions appended to their other boxes.

We also set the values of *top_mark*, *first_mark*, and *bot_mark*. The program uses the fact that *bot_mark* ≠ *null* implies *first_mark* ≠ *null*; it also knows that *bot_mark* ≡ *null* implies *top_mark* ≡ *first_mark* ≡ *null*.

The *fire_up* subroutine prepares to output the current page at the best place; then it fires up the user's output routine, if there is one, or it simply ships out the page. There is one parameter, *c*, which represents the node that was being contributed to the page when the decision to force an output was made.

⟨Declare the procedure called *fire_up* 1012⟩ ≡
  static void *fire_up*(**pointer** *c*)
  { **pointer** *p*, *q*, *r*, *s*;   ▷ nodes being examined and/or changed ◁
    pointer *prev_p*;   ▷ predecessor of *p* ◁
    int *n*;   ▷ insertion box number ◁
    bool *wait*;   ▷ should the present insertion be held over? ◁
    int *save_vbadness*;   ▷ saved value of *vbadness* ◁
    scaled *save_vfuzz*;   ▷ saved value of *vfuzz* ◁
    pointer *save_split_top_skip*;   ▷ saved value of *split_top_skip* ◁
    ⟨Set the value of *output_penalty* 1013⟩;
    if (*sa_mark* ≠ *null*)
      if (*do_marks*(*fire_up_init*, 0, *sa_mark*)) *sa_mark* ← *null*;
    if (*bot_mark* ≠ *null*) { **if** (*top_mark* ≠ *null*) *delete_token_ref*(*top_mark*);
      top_mark ← *bot_mark*; *add_token_ref*(*top_mark*); *delete_token_ref*(*first_mark*);
      first_mark ← *null*;
    }
    ⟨Put the optimal current page into box 255, update *first_mark* and *bot_mark*, append insertions to
        their boxes, and put the remaining nodes back on the contribution list 1014⟩;
    if (*sa_mark* ≠ *null*)
      if (*do_marks*(*fire_up_done*, 0, *sa_mark*)) *sa_mark* ← *null*;
    if ((*top_mark* ≠ *null*) ∧ (*first_mark* ≡ *null*)) { *first_mark* ← *top_mark*; *add_token_ref*(*top_mark*);
    }
    if (*output_routine* ≠ *null*)
      if (*dead_cycles* ≥ *max_dead_cycles*)
        ⟨Explain that too many dead cycles have occurred in a row 1024⟩
      else ⟨Fire up the user's output routine and **return** 1025⟩;
    ⟨Perform the default output routine 1023⟩;
  }

1013.   ⟨Set the value of *output_penalty* 1013⟩ ≡
  if (*type*(*best_page_break*) ≡ *penalty_node*) {
    geq_word_define(*int_base* + *output_penalty_code*, *penalty*(*best_page_break*));
    penalty(*best_page_break*) ← *inf_penalty*;
  }
  else *geq_word_define*(*int_base* + *output_penalty_code*, *inf_penalty*)
This code is used in section 1012.

1014.   As the page is finally being prepared for output, pointer p runs through the vlist, with *prev_p* trailing behind; pointer q is the tail of a list of insertions that are being held over for a subsequent page.

⟨Put the optimal current page into box 255, update *first_mark* and *bot_mark*, append insertions to their
      boxes, and put the remaining nodes back on the contribution list 1014⟩ ≡
  if (c ≡ *best_page_break*) *best_page_break* ← *null*;   ▷ c not yet linked in ◁
  ⟨Ensure that box 255 is empty before output 1015⟩;
  insert_penalties ← 0;   ▷ this will count the number of insertions held over ◁
  save_split_top_skip ← *split_top_skip*;
  if (*holding_inserts* ≤ 0) ⟨Prepare all the boxes involved in insertions to act as queues 1018⟩;
  q ← *hold_head*; *link*(q) ← *null*; *prev_p* ← *page_head*; p ← *link*(*prev_p*);
  while (p ≠ *best_page_break*) { **if** (*type*(p) ≡ *ins_node*) { **if** (*holding_inserts* ≤ 0)
      ⟨Either insert the material specified by node p into the appropriate box, or hold it for the next
        page; also delete node p from the current page 1020⟩;
    }
  else if (*type*(p) ≡ *mark_node*)
    if (*mark_class*(p) ≠ 0) ⟨Update the current marks for *fire_up* 1514⟩
    else ⟨Update the values of *first_mark* and *bot_mark* 1016⟩;
    prev_p ← p; p ← *link*(*prev_p*);
  }
  split_top_skip ← *save_split_top_skip*; ⟨Break the current page at node p, put it in box 255, and put the
      remaining nodes on the contribution list 1017⟩;
  ⟨Delete the page-insertion nodes 1019⟩
This code is used in section 1012.

1015.   ⟨Ensure that box 255 is empty before output 1015⟩ ≡
  if (*box*(255) ≠ *null*) { *print_err*(""); *print_esc*("box"); *print*("255␣is␣not␣void");
    help2("You␣shouldn't␣use␣\\box255␣except␣in␣\\output␣routines.",
    "Proceed,␣and␣I'll␣discard␣its␣present␣contents."); *box_error*(255);
  }
This code is used in section 1014.

1016.   ⟨Update the values of *first_mark* and *bot_mark* 1016⟩ ≡
  { **if** (*first_mark* ≡ *null*) { *first_mark* ← *mark_ptr*(p); *add_token_ref*(*first_mark*);
    }
    if (*bot_mark* ≠ *null*) *delete_token_ref*(*bot_mark*);
    bot_mark ← *mark_ptr*(p); *add_token_ref*(*bot_mark*);
  }
This code is used in section 1014.

1017.   When the following code is executed, the current page runs from node $link(page\_head)$ to node $prev\_p$, and the nodes from p to $page\_tail$ are to be placed back at the front of the contribution list. Furthermore the heldover insertions appear in a list from $link(hold\_head)$ to q; we will put them into the current page list for safekeeping while the user's output routine is active. We might have $q \equiv hold\_head$; and $p \equiv null$ if and only if $prev\_p \equiv page\_tail$. Error messages are suppressed within $vpackage$, since the box might appear to be overfull or underfull simply because the stretch and shrink from the \skip registers for inserts are not actually present in the box.

⟨Break the current page at node p, put it in box 255, and put the remaining nodes on the contribution
        list 1017⟩ ≡
  if $(p \neq null)$ { **if** $(link(contrib\_head) \equiv null)$
        if $(nest\_ptr \equiv 0)$ $tail \leftarrow page\_tail$;
        else $contrib\_tail \leftarrow page\_tail$;
      $link(page\_tail) \leftarrow link(contrib\_head)$; $link(contrib\_head) \leftarrow p$; $link(prev\_p) \leftarrow null$;
  }
  $save\_vbadness \leftarrow vbadness$; $vbadness \leftarrow inf\_bad$; $save\_vfuzz \leftarrow vfuzz$; $vfuzz \leftarrow max\_dimen$;
    ▷ inhibit error messages ◁
  $box(255) \leftarrow vpackage(link(page\_head), best\_size, 0, 0, exactly, page\_max\_depth)$;
  $vbadness \leftarrow save\_vbadness$; $vfuzz \leftarrow save\_vfuzz$;
  if $(last\_glue \neq max\_halfword)$ $delete\_glue\_ref(last\_glue)$;
  ⟨Start a new current page 991⟩;   ▷ this sets $last\_glue \leftarrow max\_halfword$ ◁
  if $(q \neq hold\_head)$ { $link(page\_head) \leftarrow link(hold\_head)$; $page\_tail \leftarrow q$;
  }
This code is used in section 1014.

1018.   If many insertions are supposed to go into the same box, we want to know the position of the last node in that box, so that we don't need to waste time when linking further information into it. The $last\_ins\_ptr$ fields of the page insertion nodes are therefore used for this purpose during the packaging phase.

⟨Prepare all the boxes involved in insertions to act as queues 1018⟩ ≡
  { $r \leftarrow link(page\_ins\_head)$;
    while $(r \neq page\_ins\_head)$ { **if** $(best\_ins\_ptr(r) \neq null)$ { $n \leftarrow qo(subtype(r))$; $ensure\_vbox(n)$;
        if $(box(n) \equiv null)$ $box(n) \leftarrow new\_null\_box()$;
        $p \leftarrow box(n) + list\_offset$;
        while $(link(p) \neq null)$ $p \leftarrow link(p)$;
        $last\_ins\_ptr(r) \leftarrow p$;
      }
      $r \leftarrow link(r)$;
    }
  }
This code is used in section 1014.

1019.   ⟨Delete the page-insertion nodes 1019⟩ ≡
  $r \leftarrow link(page\_ins\_head)$;
  while $(r \neq page\_ins\_head)$ { $q \leftarrow link(r)$; $free\_node(r, page\_ins\_node\_size)$; $r \leftarrow q$;
  }
  $link(page\_ins\_head) \leftarrow page\_ins\_head$
This code is used in section 1014.

1020.   We will set $best\_ins\_ptr \leftarrow null$ and package the box corresponding to insertion node r, just after making the final insertion into that box. If this final insertion is '$split\_up$', the remainder after splitting and pruning (if any) will be carried over to the next page.

⟨ Either insert the material specified by node p into the appropriate box, or hold it for the next page; also
        delete node p from the current page 1020 ⟩ ≡
  { $r \leftarrow link(page\_ins\_head)$;
    while $(subtype(r) \neq subtype(p))$ $r \leftarrow link(r)$;
    if $(best\_ins\_ptr(r) \equiv null)$ $wait \leftarrow true$;
    else { $wait \leftarrow false$; $s \leftarrow last\_ins\_ptr(r)$; $link(s) \leftarrow ins\_ptr(p)$;
      if $(best\_ins\_ptr(r) \equiv p)$ ⟨ Wrap up the box specified by node r, splitting node p if called for; set
           $wait$: $\leftarrow true$ if node p holds a remainder after splitting 1021 ⟩
      else { **while** $(link(s) \neq null)$ $s \leftarrow link(s)$;
        $last\_ins\_ptr(r) \leftarrow s$;
      }
    }
    ⟨ Either append the insertion node p after node q, and remove it from the current page, or delete
      $node(p)$ 1022 ⟩;
  }

This code is used in section 1014.

1021.   ⟨ Wrap up the box specified by node r, splitting node p if called for; set $wait$: $\leftarrow true$ if node p
        holds a remainder after splitting 1021 ⟩ ≡
  { **if** $(type(r) \equiv split\_up)$
    if $((broken\_ins(r) \equiv p) \wedge (broken\_ptr(r) \neq null))$ { **while** $(link(s) \neq broken\_ptr(r))$ $s \leftarrow link(s)$;
      $link(s) \leftarrow null$; $split\_top\_skip \leftarrow split\_top\_ptr(p)$;
      $ins\_ptr(p) \leftarrow prune\_page\_top(broken\_ptr(r), false)$;
      if $(ins\_ptr(p) \neq null)$ { $temp\_ptr \leftarrow vpack(ins\_ptr(p), natural)$;
        $height(p) \leftarrow height(temp\_ptr) + depth(temp\_ptr)$; $list\_ptr(temp\_ptr) \leftarrow null$;
        $flush\_node\_list(temp\_ptr)$; $wait \leftarrow true$;
      }
    }
    $best\_ins\_ptr(r) \leftarrow null$; $n \leftarrow qo(subtype(r))$; $temp\_ptr \leftarrow list\_ptr(box(n))$; $list\_ptr(box(n)) \leftarrow null$;
    $flush\_node\_list(box(n))$; $box(n) \leftarrow vpack(temp\_ptr, natural)$;
  }

This code is used in section 1020.

1022.   ⟨ Either append the insertion node p after node q, and remove it from the current page, or delete
        $node(p)$ 1022 ⟩ ≡
  $link(prev\_p) \leftarrow link(p)$; $link(p) \leftarrow null$;
  if $(wait)$ { $link(q) \leftarrow p$; $q \leftarrow p$; $incr(insert\_penalties)$;
  }
  else { $delete\_glue\_ref(split\_top\_ptr(p))$; $free\_node(p, ins\_node\_size)$;
  }
  $p \leftarrow prev\_p$

This code is used in section 1020.

1023.   The list of heldover insertions, running from $link(page\_head)$ to $page\_tail$, must be moved to the contribution list when the user has specified no output routine.

⟨ Perform the default output routine 1023 ⟩ ≡
   { **if** $(link(page\_head) \neq null)$ { **if** $(link(contrib\_head) \equiv null)$
         if $(nest\_ptr \equiv 0)$ $tail \leftarrow page\_tail$; **else** $contrib\_tail \leftarrow page\_tail$;
      else $link(page\_tail) \leftarrow link(contrib\_head)$;
      $link(contrib\_head) \leftarrow link(page\_head)$; $link(page\_head) \leftarrow null$; $page\_tail \leftarrow page\_head$;
   }
   $flush\_node\_list(page\_disc)$; $page\_disc \leftarrow null$; $ship\_out(box(255))$; $box(255) \leftarrow null$;
   }

This code is used in section 1012.

1024.   ⟨ Explain that too many dead cycles have occurred in a row 1024 ⟩ ≡
   { $print\_err($ "Output␣loop−−−" $)$; $print\_int(dead\_cycles)$; $print($ "␣consecutive␣dead␣cycles" $)$;
      $help3($ "I've␣concluded␣that␣your␣\\output␣is␣awry;␣it␣never␣does␣a",
      "\\shipout,␣so␣I'm␣shipping␣\\box255␣out␣myself.␣Next␣time",
      "increase␣\\maxdeadcycles␣if␣you␣want␣me␣to␣be␣more␣patient!" $)$; $error()$;
   }

This code is used in section 1012.

1025.   ⟨ Fire up the user's output routine and **return** 1025 ⟩ ≡
   { $output\_active \leftarrow true$; $incr(dead\_cycles)$; $push\_nest()$; $mode \leftarrow -vmode$;
      $prev\_depth \leftarrow ignore\_depth$; $mode\_line \leftarrow -line$; $begin\_token\_list(output\_routine, output\_text)$;
      $new\_save\_level(output\_group)$; $normal\_paragraph()$; $scan\_left\_brace()$; **return**;
   }

This code is used in section 1012.

1026.   When the user's output routine finishes, it has constructed a vlist in internal vertical mode, and TEX will do the following:

⟨ Resume the page builder after an output routine has come to an end 1026 ⟩ ≡
   { **if** $((loc \neq null) \vee ((token\_type \neq output\_text) \wedge (token\_type \neq backed\_up)))$
         ⟨ Recover from an unbalanced output routine 1027 ⟩;
      $end\_token\_list()$;   ▷ conserve stack space in case more outputs are triggered ◁
      $end\_graf()$; $unsave()$; $output\_active \leftarrow false$; $insert\_penalties \leftarrow 0$;
      ⟨ Ensure that box 255 is empty after output 1028 ⟩;
      if $(tail \neq head)$ ▷ current list goes after heldover insertions ◁
      { $link(page\_tail) \leftarrow link(head)$; $page\_tail \leftarrow tail$;
      }
      if $(link(page\_head) \neq null)$ ▷ and both go before heldover contributions ◁
      { **if** $(link(contrib\_head) \equiv null)$ $contrib\_tail \leftarrow page\_tail$;
         $link(page\_tail) \leftarrow link(contrib\_head)$; $link(contrib\_head) \leftarrow link(page\_head)$;
         $link(page\_head) \leftarrow null$; $page\_tail \leftarrow page\_head$;
      }
      $flush\_node\_list(page\_disc)$; $page\_disc \leftarrow null$; $pop\_nest()$; $build\_page()$;
   }

This code is used in section 1100.

1027. ⟨Recover from an unbalanced output routine 1027⟩ ≡
 { *print_err* ("Unbalanced␣output␣routine");
  help2 ("Your␣sneaky␣output␣routine␣has␣problematic␣{'s␣and/or␣}'s.",
  "I␣can't␣handle␣that␣very␣well;␣good␣luck."); *error* ( );
  do *get_token* ( ); **while** (¬(*loc* ≡ *null*));
 } ▷ loops forever if reading from a file, since *null* ≡ *min_halfword* ≤ 0 ◁

This code is used in section 1026.

1028. ⟨Ensure that box 255 is empty after output 1028⟩ ≡
 if (*box*(255) ≠ *null*) { *print_err* ("Output␣routine␣didn't␣use␣all␣of␣"); *print_esc* ("box");
  print_int (255); *help3* ("Your␣\\output␣commands␣should␣empty␣\\box255,",
  "e.g.,␣by␣saying␣'\\shipout\\box255'.",
  "Proceed;␣I'll␣discard␣its␣present␣contents."); *box_error* (255);
 }

This code is used in section 1026.

1029.   The chief executive.   We come now to the *main_control* routine, which contains the master switch that causes all the various pieces of TEX to do their things, in the right order.

In a sense, this is the grand climax of the program: It applies all the tools that we have worked so hard to construct. In another sense, this is the messiest part of the program: It necessarily refers to other pieces of code all over the place, so that a person can't fully understand what is going on without paging back and forth to be reminded of conventions that are defined elsewhere. We are now at the hub of the web, the central nervous system that touches most of the other parts and ties them together.

The structure of *main_control* itself is quite simple. There's a label called *big_switch*, at which point the next token of input is fetched using *get_x_token*. Then the program branches at high speed into one of about 100 possible directions, based on the value of the current mode and the newly fetched command code; the sum $abs(mode) + cur\_cmd$ indicates what to do next. For example, the case '*vmode + letter*' arises when a letter occurs in vertical mode (or internal vertical mode); this case leads to instructions that initialize a new paragraph and enter horizontal mode.

The big **case** statement that contains this multiway switch has been labeled *reswitch*, so that the program can **goto** *reswitch* when the next token has already been fetched. Most of the cases are quite short; they call an "action procedure" that does the work for that case, and then they either **goto** *reswitch* or they "fall through" to the end of the **case** statement, which returns control back to *big_switch*. Thus, *main_control* is not an extremely large procedure, in spite of the multiplicity of things it must do; it is small enough to be handled by Pascal compilers that put severe restrictions on procedure size.

One case is singled out for special treatment, because it accounts for most of TEX's activities in typical applications. The process of reading simple text and converting it into *char_node* records, while looking for ligatures and kerns, is part of TEX's "inner loop"; the whole program runs efficiently when its inner loop is fast, so this part has been written with particular care.

1030.   We shall concentrate first on the inner loop of *main_control*, deferring consideration of the other cases until later.

⟨ Declare action procedures for use by *main_control* 1043 ⟩
⟨ Declare the procedure called *handle_right_brace* 1068 ⟩
  static void *main_control*(**void**)   ▷ governs TEX's activities ◁
  { **int** *t*;   ▷ general-purpose temporary variable ◁

    if (*every_job* ≠ *null*) *begin_token_list*(*every_job*, *every_job_text*);
  big_switch: *get_x_token*( );
  reswitch: ⟨ Give diagnostic information, if requested 1031 ⟩;
    switch (*abs*(*mode*) + *cur_cmd*) {
    case *hmode* + *letter*: **case** *hmode* + *other_char*: **case** *hmode* + *char_given*: **goto** *main_loop*;
    case *hmode* + *char_num*:
      { *scan_char_num*( ); *cur_chr* ← *cur_val*; **goto** *main_loop*; }
    case *hmode* + *no_boundary*:
      { *get_x_token*( );
        if ((*cur_cmd* ≡ *letter*) ∨ (*cur_cmd* ≡ *other_char*) ∨ (*cur_cmd* ≡ *char_given*) ∨ (*cur_cmd* ≡
            char_num)) *cancel_boundary* ← *true*;
        goto *reswitch*;
      }
    case *hmode* + *spacer*:
      if (*space_factor* ≡ 1000) **goto** *append_normal_space*;
      else *app_space*( ); **break**;
    case *hmode* + *ex_space*: **case** *mmode* + *ex_space*: **goto** *append_normal_space*;
    ⟨ Cases of *main_control* that are not part of the inner loop 1045 ⟩
    }   ▷ of the big **case** statement ◁
    goto *big_switch*;
  main_loop: ⟨ Append character *cur_chr* and the following characters (if any) to the current hlist in the
      current font; **goto** *reswitch* when a non-character has been fetched 1034 ⟩;
  append_normal_space:
    ⟨ Append a normal inter-word space to the current list, then **goto** *big_switch* 1041 ⟩;
  }

1031.   When a new token has just been fetched at *big_switch*, we have an ideal place to monitor TEX's activity.

⟨ Give diagnostic information, if requested 1031 ⟩ ≡
  if (*interrupt* ≠ 0)
    if (*OK_to_interrupt*) { *back_input*( ); *check_interrupt*; **goto** *big_switch*;
    }
#**ifdef** DEBUG
  if (*panicking*) *check_mem*(*false*);
#**endif**
  if (*tracing_commands* > 0) *show_cur_cmd_chr*( )
This code is used in section 1030.

1032. The following part of the program was first written in a structured manner, according to the philosophy that "premature optimization is the root of all evil." Then it was rearranged into pieces of spaghetti so that the most common actions could proceed with little or no redundancy.

The original unoptimized form of this algorithm resembles the *reconstitute* procedure, which was described earlier in connection with hyphenation. Again we have an implied "cursor" between characters *cur_l* and *cur_r*. The main difference is that the *lig_stack* can now contain a charnode as well as pseudo-ligatures; that stack is now usually nonempty, because the next character of input (if any) has been appended to it. In *main_control* we have

$$cur\_r = \begin{cases} character(lig\_stack), & \text{if } lig\_stack > null; \\ font\_bchar[cur\_font], & \text{otherwise;} \end{cases}$$

except when $character(lig\_stack) \equiv font\_false\_bchar[cur\_font]$. Several additional global variables are needed.

⟨ Global variables 13 ⟩ +≡
  static internal_font_number *main_f*;   ▷ the current font ◁
  static four_quarters *main_i*;   ▷ character information bytes for *cur_l* ◁
  static four_quarters *main_j*;   ▷ ligature/kern command ◁
  static font_index *main_k*;   ▷ index into *font_info* ◁
  static pointer *main_p*;   ▷ temporary register for list manipulation ◁
  static int *main_s*;   ▷ space factor value ◁
  static halfword *bchar*;   ▷ boundary character of current font, or *non_char* ◁
  static halfword *false_bchar*;   ▷ nonexistent character matching *bchar*, or *non_char* ◁
  static bool *cancel_boundary*;   ▷ should the left boundary be ignored? ◁
  static bool *ins_disc*;   ▷ should we insert a discretionary node? ◁

1033. The boolean variables of the main loop are normally false, and always reset to false before the loop is left. That saves us the extra work of initializing each time.

⟨ Set initial values of key variables 21 ⟩ +≡
  ligature_present ← *false*; *cancel_boundary* ← *false*; *lft_hit* ← *false*; *rt_hit* ← *false*; *ins_disc* ← *false*;

1034. We leave the *space_factor* unchanged if $sf\_code(cur\_chr) \equiv 0$; otherwise we set it equal to $sf\_code(cur\_chr)$, except that it should never change from a value less than 1000 to a value exceeding 1000. The most common case is $sf\_code(cur\_chr) \equiv 1000$, so we want that case to be fast.

The overall structure of the main loop is presented here. Some program labels are inside the individual sections.

#**define** *adjust_space_factor*
       $main\_s \leftarrow sf\_code(cur\_chr)$;
       if $(main\_s \equiv 1000)$ $space\_factor \leftarrow 1000$;
       else if $(main\_s < 1000)$ { **if** $(main\_s > 0)$ $space\_factor \leftarrow main\_s$;
       }
       else if $(space\_factor < 1000)$ $space\_factor \leftarrow 1000$;
       else $space\_factor \leftarrow main\_s$

⟨ Append character *cur_chr* and the following characters (if any) to the current hlist in the current font;
      goto *reswitch* when a non-character has been fetched 1034 ⟩ ≡
  adjust_space_factor;

    ▷ this prevents spurious ligatures ◁

This code is used in section 1034.

1039.   Even though comparatively few characters have a lig/kern program, several of the instructions here count as part of TEX's inner loop, since a potentially long sequential search must be performed. For example, tests with Computer Modern Roman showed that about 40 per cent of all characters actually encountered in practice had a lig/kern program, and that about four lig/kern commands were investigated for every such character.

At the beginning of this code we have $main\_i \equiv char\_info(main\_f, cur\_l)$.

⟨If there's a ligature/kern command relevant to cur_l and cur_r, adjust the text appropriately; exit to $main\_loop\_wrapup$ 1039⟩ ≡
  if $(char\_tag(main\_i) \neq lig\_tag)$ **goto** $main\_loop\_wrapup$;
  if $(cur\_r \equiv non\_char)$ **goto** $main\_loop\_wrapup$;

     $main\_k \leftarrow bchar\_label[main\_f]$; **goto** *main_lig_loop1*;
   }

This code is used in section 1039.

1041.   The occurrence of blank spaces is almost part of TEX's inner loop, since we usually encounter about one space for every five non-blank characters. Therefore *main_control* gives second-highest priority to ordinary spaces.

When a glue parameter like `\spaceskip` is set to '0pt', we will see to it later that the corresponding glue specification is precisely *zero_glue*, not merely a pointer to some specification that happens to be full of zeroes. Therefore it is simple to test whether a glue parameter is zero or not.

⟨ Append a normal inter-word space to the current list, then **goto** *big_switch* 1041 ⟩ ≡
   if (*space_skip* ≡ *zero_glue*) {
      ⟨ Find the glue specification, *main_p*, for text spaces in the current font 1042 ⟩;
      temp_ptr ← *new_glue*(*main_p*);
   }
   else *temp_ptr* ← *new_param_glue*(*space_skip_code*);
   link(*tail*) ← *temp_ptr*; *tail* ← *temp_ptr*; **goto** *big_switch*

This code is used in section 1030.

1042.   Having *font_glue* allocated for each text font saves both time and memory. If any of the three spacing parameters are subsequently changed by the use of `\fontdimen`, the *find_font_dimen* procedure deallocates the *font_glue* specification allocated here.

⟨ Find the glue specification, *main_p*, for text spaces in the current font 1042 ⟩ ≡
   { *main_p* ← *font_glue*[*cur_font*];
     if (*main_p* ≡ *null*) { *main_p* ← *new_spec*(*zero_glue*); *main_k* ← *param_base*[*cur_font*] + *space_code*;

   static void *insert_dollar_sign*(**void**)
   { *back_input*( ); *cur_tok* ← *math_shift_token* + '$'; *print_err*("Missing␣$␣inserted");
     help2("I'␣ve␣inserted␣a␣begin-math/end-math␣symbol␣since␣I␣think",
     "you␣left␣one␣out.␣Proceed,␣with␣fingers␣crossed."); *ins_error*( );
   }

1048.   When erroneous situations arise, TEX usually issues an error message specific to the particular error. For example, '\noalign' should not appear in any mode, since it is recognized by the *align_peek* routine in all of its legitimate appearances; a special error message is given when '\noalign' occurs elsewhere. But sometimes the most appropriate error message is simply that the user is not allowed to do what he or she has attempted. For example, '\moveleft' is allowed only in vertical mode, and '\lower' only in non-vertical modes. Such cases are enumerated here and in the other sections referred to under 'See also . . . .'

⟨ Forbidden cases detected in *main_control* 1048 ⟩ ≡
   case *vmode* + *vmove*: **case** *hmode* + *hmove*: **case** *mmode* + *hmove*: *any_mode*(*last_item*):
See also sections 1098, 1111, and 1144.
This code is used in section 1045.

1049.   The '*you_cant*' procedure prints a line saying that the current command is illegal in the current mode; it identifies these things symbolically.

⟨ Declare action procedures for use by *main_control* 1043 ⟩ +≡
  static void *you_cant*(**void**)
  { *print_err*("You␣can't␣use␣'"); *print_cmd_chr*(*cur_cmd*, *cur_chr*); *print*("'␣in␣");
    print_mode(*mode*);
  }

1050.   ⟨ Declare action procedures for use by *main_control* 1043 ⟩ +≡
  static void *report_illegal_case*(**void**)
  { *you_cant*( ); *help4*("Sorry,␣but␣I'm␣not␣programmed␣to␣handle␣this␣case;",
    "I'll␣just␣pretend␣that␣you␣didn't␣ask␣for␣it.",
    "If␣you're␣in␣the␣wrong␣mode,␣you␣might␣be␣able␣to",
    "return␣to␣the␣right␣one␣by␣typing␣'I}'␣or␣'I\$'␣or␣'I\\par'.");
    error( );
  }

1051.   Some operations are allowed only in privileged modes, i.e., in cases that $mode > 0$. The *privileged* function is used to detect violations of this rule; it issues an error message and returns *false* if the current *mode* is negative.

⟨ Declare action procedures for use by *main_control* 1043 ⟩ +≡
  static bool *privileged*(**void**)
  { **if** ($mode > 0$) **return** *true*;
    else { *report_illegal_case*( ); **return** *false*;
    }
  }

1052.   Either \dump or \end will cause *main_control* to enter the endgame, since both of them have '*stop*' as their command code.

⟨ Put each of TEX's primitives into the hash table 226 ⟩ +≡
  primitive("end", *stop*, 0);
  primitive("dump", *stop*, 1);

1053.   ⟨ Cases of *print_cmd_chr* for symbolic printing of primitives 227 ⟩ +≡
case *stop*:
  if ($chr\_code \equiv 1$) *print_esc*("dump"); **else** *print_esc*("end"); **break**;

1054. We don't want to leave *main_control* immediately when a *stop* command is sensed, because it may be necessary to invoke an \output routine several times before things really grind to a halt. (The output routine might even say '\gdef\end{...}', to prolong the life of the job.) Therefore *its_all_over* is *true* only when the current page and contribution list are empty, and when the last output was not a "dead cycle."

⟨ Declare action procedures for use by *main_control* 1043 ⟩ +≡

1055. Building boxes and lists. The most important parts of *main_control* are concerned with TeX's chief mission of box-making. We need to control the activities that put entries on vlists and hlists, as well as the activities that convert those lists into boxes. All of the necessary machinery has already been developed; it remains for us to "push the buttons" at the right times.

1056. As an introduction to these routines, let's consider one of the simplest cases: What happens when '\hrule' occurs in vertical mode, or '\vrule' in horizontal mode or math mode? The code in *main_control* is short, since the *scan_rule_spec* routine already does most of what is required; thus, there is no need for a special action procedure.

Note that baselineskip calculations are disabled after a rule in vertical mode, by setting *prev_depth* ← *ignore_depth*.

⟨ Cases of *main_control* that build boxes and lists 1056 ⟩ ≡
case *vmode* + *hrule*: **case** *hmode* + *vrule*: **case** *mmode* + *vrule*:
  { *tail_append*(*scan_rule_spec*( ));
    if (*abs*(*mode*) ≡ *vmode*) *prev_depth* ← *ignore_depth*;
    else if (*abs*(*mode*) ≡ *hmode*) *space_factor* ← 1000;
  } **break**;

See also sections 1057, 1063, 1067, 1073, 1090, 1092, 1094, 1097, 1102, 1104, 1109, 1112, 1116, 1122, 1126, 1130, 1134, 1137, 1140, 1150, 1154, 1158, 1162, 1164, 1167, 1171, 1175, 1180, 1190, and 1193.

This code is used in section 1045.

1057. The processing of things like \hskip and \vskip is slightly more complicated. But the code in *main_control* is very short, since it simply calls on the action routine *append_glue*. Similarly, \kern activates *append_kern*.

⟨ Cases of *main_control* that build boxes and lists 1056 ⟩ +≡
case *vmode* + *vskip*: **case** *hmode* + *hskip*: **case** *mmode* + *hskip*: **case** *mmode* + *mskip*: *append_glue*( );
  break;
any_mode(*kern*): **case** *mmode* + *mkern*: *append_kern*( ); **break**;

1058. The *hskip* and *vskip* command codes are used for control sequences like \hss and \vfil as well as for \hskip and \vskip. The difference is in the value of *cur_chr*.

#**define** *fil_code* 0   ▷ identifies \hfil and \vfil ◁

1060. All the work relating to glue creation has been relegated to the following subroutine. It does not call *build_page*, because it is used in at least one place where that would be a mistake.

⟨Declare action procedures for use by *main_control* 1043⟩ +≡
  static void *append_glue*(**void**)
  { **small_number** *s*;   ▷ modifier of skip command ◁

    s ← *cur_chr*;
    switch (*s*) {
    case *fil_code*: *cur_val* ← *fil_glue*; **break**;
    case *fill_code*: *cur_val* ← *fill_glue*; **break**;
    case *ss_code*: *cur_val* ← *ss_glue*; **break**;
    case *fil_neg_code*: *cur_val* ← *fil_neg_glue*; **break**;
    case *skip_code*: *scan_glue*(*glue_val*); **break**;
    case *mskip_code*: *scan_glue*(*mu_val*);
    }   ▷ now *cur_val* points to the glue specification ◁
    tail_append(*new_glue*(*cur_val*));
    if (*s* ≥ *skip_code*) { *decr*(*glue_ref_count*(*cur_val*));
      if (*s* > *skip_code*) *subtype*(*tail*) ← *mu_glue*;
    }
  }

1061. ⟨Declare action procedures for use by *main_control* 1043⟩ +≡
  static void *append_kern*(**void**)
  { **quarterword** *s*;   ▷ *subtype* of the kern node ◁

    s ← *cur_chr*; *scan_dimen*(*s* ≡ *mu_glue*, *false*, *false*); *tail_append*(*new_kern*(*cur_val*));
    subtype(*tail*) ← *s*;
  }

1062.   Many of the actions related to box-making are triggered by the appearance of braces in the input. For example, when the user says '\hbox to 100pt{⟨hlist⟩}' in vertical mode, the information about the box size (100pt, *exactly*) is put onto *save_stack* with a level boundary word just above it, and *cur_group* ← *adjusted_hbox_group*; TeX enters restricted horizontal mode to process the hlist. The right brace eventually causes *save_stack* to be restored to its former state, at which time the information about the box size (100pt, *exactly*) is available once again; a box is packaged and we leave restricted horizontal mode, appending the new box to the current list of the enclosing mode (in this case to the current list of vertical mode), followed by any vertical adjustments that were removed from the box by *hpack*.

The next few sections of the program are therefore concerned with the treatment of left and right curly braces.

1063.   If a left brace occurs in the middle of a page or paragraph, it simply introduces a new level of grouping, and the matching right brace will not have such a drastic effect. Such grouping affects neither the mode nor the current list.

⟨Cases of *main_control* that build boxes and lists 1056⟩ +≡
non_math(*left_brace*): *new_save_level*(*simple_group*); **break**;
any_mode(*begin_group*): *new_save_level*(*semi_simple_group*); **break**;
any_mode(*end_group*):
  if (*cur_group* ≡ *semi_simple_group*) *unsave*( );
  else *off_save*( ); **break**;

1064.   We have to deal with errors in which braces and such things are not properly nested. Sometimes the user makes an error of commission by inserting an extra symbol, but sometimes the user makes an error of omission. TeX can't always tell one from the other, so it makes a guess and tries to avoid getting into a loop.

The *off_save* routine is called when the current group code is wrong. It tries to insert something into the user's input that will help clean off the top level.

⟨Declare action procedures for use by *main_control* 1043⟩ +≡
  static void *off_save*(**void**)
  { **pointer** *p*;   ▷ inserted token ◁

    if (*cur_group* ≡ *bottom_level*) ⟨Drop current token and complain that it was unmatched 1066⟩
    else { *back_input*( ); *p* ← *get_avail*( ); *link*(*temp_head*) ← *p*; *print_err*("Missing␣");
      ⟨Prepare to insert a token that matches *cur_group*, and print what it is 1065⟩;
      print("␣inserted"); *ins_list*(*link*(*temp_head*));
      help5("I've␣inserted␣something␣that␣you␣may␣have␣forgotten.",
      "(See␣the␣<inserted␣text>␣above.)",
      "With␣luck,␣this␣will␣get␣me␣unwedged.␣But␣if␣you",
      "really␣didn't␣forget␣anything,␣try␣typing␣'2'␣now;␣then",
      "my␣insertion␣and␣my␣current␣dilemma␣will␣both␣disappear."); *error*( );
    }
  }

1065. At this point, $link(temp\_head) \equiv p$, a pointer to an empty one-word node.

⟨ Prepare to insert a token that matches cur_group, and print what it is 1065 ⟩ ≡
  switch (cur_group) {
  case $semi\_simple\_group$:
    { $info(p) \leftarrow cs\_token\_flag + frozen\_end\_group$; $print\_esc("endgroup")$;

    $error( )$;
  }

This code is used in section 1064.

1067. The routine for a $right\_brace$ character branches into many subcases, since a variety of things may happen, depending on cur_group. Some types of groups are not supposed to be ended by a right brace; error messages are given in hopes of pinpointing the problem. Most branches of this routine will be filled in later, when we are ready to understand them; meanwhile, we must prepare ourselves to deal with such errors.

⟨ Cases of $main\_control$ that build boxes and lists 1056 ⟩ +≡

  }

1070.   Here is where we clear the parameters that are supposed to revert to their default values after every
paragraph and when internal vertical mode is entered.

⟨ Declare action procedures for use by *main_control* 1043 ⟩ +≡

  static void *normal_paragraph*(**void**)
  { **if** (*looseness* ≠ 0) *eq_word_define*(*int_base* + *looseness_code*, 0);
    if (*hang_indent* ≠ 0) *eq_word_define*(*dimen_base* + *hang_indent_code*, 0);
    if (*hang_after* ≠ 1) *eq_word_define*(*int_base* + *hang_after_code*, 1);
    if (*par_shape_ptr* ≠ *null*) *eq_define*(*par_shape_loc*, *shape_ref*, *null*);
    if (*inter_line_penalties_ptr* ≠ *null*) *eq_define*(*inter_line_penalties_loc*, *shape_ref*, *null*);
  }

1071.   Now let's turn to the question of how \hbox is treated.   We actually need to consider also a slightly larger context, since constructions like '\setbox3=\hbox...' and '\leaders\hbox...' and '\lower3.8pt\hbox...' are supposed to invoke quite different actions after the box has been packaged. Conversely, constructions like '\setbox3=' can be followed by a variety of different kinds of boxes, and we would like to encode such things in an efficient way.

In other words, there are two problems: to represent the context of a box, and to represent its type.

The first problem is solved by putting a "context code" on the *save_stack*, just below the two entries that give the dimensions produced by *scan_spec*. The context code is either a (signed) shift amount, or it is a large integer $\geq$ *box_flag*, where *box_flag* $\equiv 2^{30}$. Codes *box_flag* through *global_box_flag* $- 1$ represent '\setbox0' through '\setbox32767'; codes *global_box_flag* through *ship_out_flag* $- 1$ represent '\global\setbox0' through '\global\setbox32767'; code *ship_out_flag* represents '\shipout'; and codes *leader_flag* through *leader_flag* $+ 2$ represent '\leaders', '\cleaders', and '\xleaders'.

The second problem is solved by giving the command code *make_box* to all control sequences that produce a box, and by using the following *chr_code* values to distinguish between them: *box_code*, *copy_code*, *last_box_code*, *vsplit_code*, *vtop_code*, *vtop_code* $+$ *vmode*, and *vtop_code* $+$ *hmode*, where the latter two are used to denote \vbox and \hbox, respectively.

#**define** *box_flag* °*10000000000*   ▷ context code for '\setbox0' ◁

  else { $n \leftarrow info(par\_shape\_ptr)$;
    if $(prev\_graf + 2 \geq n)$ $p \leftarrow par\_shape\_ptr + 2 * n$;
    else $p \leftarrow par\_shape\_ptr + 2 * (prev\_graf + 2)$;
    $s \leftarrow mem[p-1].sc$; $l \leftarrow mem[p].sc$; $cur\_hfactor \leftarrow 0$;
  }

This code is used in section 1145.

1150.   Subformulas of math formulas cause a new level of math mode to be entered, on the semantic nest as well as the save stack. These subformulas arise in several ways: (1) A left brace by itself indicates the beginning of a subformula that will be put into a box, thereby freezing its glue and preventing line breaks. (2) A subscript or superscript is treated as a subformula if it is not a single character; the same applies to the nucleus of things like \underline. (3) The \left primitive initiates a subformula that will be terminated by a matching \right. The group codes placed on *save_stack* in these three cases are *math_group*, *math_group*, and *math_left_group*, respectively.

Here is the code that handles case (1); the other cases are not quite as trivial, so we shall consider them later.

⟨ Cases of *main_control* that build boxes and lists 1056 ⟩ +≡
case *mmode* + *left_brace*:
  { *tail_append*(*new_noad*( )); *back_input*( ); *scan_math*(*nucleus*(*tail*));
  } **break**;

1151.   Recall that the *nucleus*, *subscr*, and *supscr* fields in a noad are broken down into subfields called *math_type* and either *info* or (*fam*, *character*). The job of *scan_math* is to figure out what to place in one of these principal fields; it looks at the subformula that comes next in the input, and places an encoding of that subformula into a given word of *mem*.

#**define** *fam_in_range*   ((*cur_fam* ≥ 0) ∧ (*cur_fam* < 16))

⟨ Declare action procedures for use by *main_control* 1043 ⟩ +≡
  static void *scan_math*(**pointer** *p*)
  { **int** *c*;   ▷ math character code ◁

  restart: ⟨ Get the next non-blank non-relax non-call token 404 ⟩;
  reswitch:
    switch (*cur_cmd*) {
    case *letter*: **case** *other_char*: **case** *char_given*:
      { *c* ← *ho*(*math_code*(*cur_chr*));
        if (*c* ≡ °*100000*) { ⟨ Treat *cur_chr* as an active character 1152 ⟩;
          goto *restart*;
        }
      } **break**;
    case *char_num*:
      { *scan_char_num*( ); *cur_chr* ← *cur_val*; *cur_cmd* ← *char_given*; **goto** *reswitch*;
      }
    case *math_char_num*:
      { *scan_fifteen_bit_int*( ); *c* ← *cur_val*;
      } **break**;
    case *math_given*: *c* ← *cur_chr*; **break**;
    case *delim_num*:
      { *scan_twenty_seven_bit_int*( ); *c* ← *cur_val*/°*10000*;
      } **break**;
    default: ⟨ Scan a subformula enclosed in braces and **return** 1153 ⟩
    }
    math_type(*p*) ← *math_char*; *character*(*p*) ← *qi*(*c* % 256);
    if ((*c* ≥ *var_code*) ∧ *fam_in_range*) *fam*(*p*) ← *cur_fam*;
    else *fam*(*p*) ← (*c*/256) % 16;
  }

1152. An active character that is an *outer_call* is allowed here.

⟨Treat *cur_chr* as an active character 1152⟩ ≡
  { *cur_cs* ← *cur_chr* + *active_base*; *cur_cmd* ← *eq_type*(*cur_cs*); *cur_chr* ← *equiv*(*cur_cs*); *x_token*( );
    back_input( );
  }

This code is used in sections 1151 and 1155.

1153. The pointer *p* is placed on *save_stack* while a complex subformula is being scanned.

⟨Scan a subformula enclosed in braces and **return** 1153⟩ ≡
  { *back_input*( ); *scan_left_brace*( );
    saved(0) ← *p*; *incr*(*save_ptr*); *push_math*(*math_group*); **return**;
  }

This code is used in section 1151.

1154. The simplest math formula is, of course, '$ $', when no noads are generated. The next simplest cases involve a single character, e.g., 'x'. Even though such cases may not seem to be very interesting, the reader can perhaps understand how happy the author was when 'x' was first properly typeset by TeX. The code in this section was used.

⟨Cases of *main_control* that build boxes and lists 1056⟩ +≡
case *mmode* + *letter*: **case** *mmode* + *other_char*: **case** *mmode* + *char_given*:
  set_math_char(*ho*(*math_code*(*cur_chr*))); **break**;
case *mmode* + *char_num*:
  { *scan_char_num*( ); *cur_chr* ← *cur_val*; *set_math_char*(*ho*(*math_code*(*cur_chr*)));
  } **break**;
case *mmode* + *math_char_num*:
  { *scan_fifteen_bit_int*( ); *set_math_char*(*cur_val*);
  } **break**;
case *mmode* + *math_given*: *set_math_char*(*cur_chr*); **break**;
case *mmode* + *delim_num*:
  { *scan_twenty_seven_bit_int*( ); *set_math_char*(*cur_val*/°*10000*);
  } **break**;

1155. The *set_math_char* procedure creates a new noad appropriate to a given math code, and appends it to the current mlist. However, if the math code is sufficiently large, the *cur_chr* is treated as an active character and nothing is appended.

⟨Declare action procedures for use by *main_control* 1043⟩ +≡
  static void *set_math_char*(**int** *c*)
  { **pointer** *p*;   ▷the new noad◁
    if (*c* ≥ °*100000*) ⟨Treat *cur_chr* as an active character 1152⟩
    else { *p* ← *new_noad*( ); *math_type*(*nucleus*(*p*)) ← *math_char*; *character*(*nucleus*(*p*)) ← *qi*(*c* % 256);
      fam(*nucleus*(*p*)) ← (*c*/256) % 16;
      if (*c* ≥ *var_code*) { **if** (*fam_in_range*) *fam*(*nucleus*(*p*)) ← *cur_fam*;
        type(*p*) ← *ord_noad*;
      }
      else *type*(*p*) ← *ord_noad* + (*c*/°*10000*);
      link(*tail*) ← *p*; *tail* ← *p*;
    }
  }

1156.   Primitive math operators like `\mathop` and `\underline` are given the command code *math_comp*, supplemented by the noad type that they generate.

⟨Put each of TEX's primitives into the hash table 226⟩ +≡
   primitive("mathord", *math_comp*, *ord_noad*); *primitive*("mathop", *math_comp*, *op_noad*);
   primitive("mathbin", *math_comp*, *bin_noad*); *primitive*("mathrel", *math_comp*, *rel_noad*);
   primitive("mathopen", *math_comp*, *open_noad*); *primitive*("mathclose", *math_comp*, *close_noad*);
   primitive("mathpunct", *math_comp*, *punct_noad*); *primitive*("mathinner", *math_comp*, *inner_noad*);
   primitive("underline", *math_comp*, *under_noad*); *primitive*("overline", *math_comp*, *over_noad*);
   primitive("displaylimits", *limit_switch*, *normal*); *primitive*("limits", *limit_switch*, *limits*);
   primitive("nolimits", *limit_switch*, *no_limits*);

1157.   ⟨Cases of *print_cmd_chr* for symbolic printing of primitives 227⟩ +≡
case *math_comp*:
   switch (*chr_code*) {
   case *ord_noad*: *print_esc*("mathord"); **break**;
   case *op_noad*: *print_esc*("mathop"); **break**;

  }
  This code is used in section 1206.

1208.   Mode-independent processing.   The long *main_control* procedure has now been fully specified, except for certain activities that are independent of the current mode. These activities do not change the current vlist or hlist or mlist; if they change anything, it is the value of a parameter or the meaning of a control sequence.

Assignments to values in *eqtb* can be global or local. Furthermore, a control sequence can be defined to be '\long', '\protected', or '\outer', and it might or might not be expanded. The prefixes '\global', '\long', '\protected', and '\outer' can occur in any order. Therefore we assign binary numeric codes, making it possible to accumulate the union of all specified prefixes by adding the corresponding codes. (Pascal's *set* operations could also have been used.)

⟨Put each of TeX's primitives into the hash table 226⟩ +≡
    primitive("long", *prefix*, 1); *primitive*("outer", *prefix*, 2); *primitive*("global", *prefix*, 4);
    primitive("def", *def*, 0); *primitive*("gdef", *def*, 1); *primitive*("edef", *def*, 2); *primitive*("xdef", *def*, 3);

1209.   ⟨Cases of *print_cmd_chr* for symbolic printing of primitives 227⟩ +≡

      selector ← *term_and_log*;
    }

This code is used in section 1293.

1299.   Dumping and undumping the tables.   After INITEX has seen a collection of fonts and macros, it can write all the necessary information on an auxiliary file so that production versions of TeX are able to initialize their memory at high speed. The present section of the program takes care of such output and input. We shall consider simultaneously the processes of storing and restoring, so that the inverse relation between them is clear.

The global variable *format_ident* is a string that is printed right after the *banner* line when TeX is ready to start. For INITEX this string says simply ' (INITEX)'; for other versions of TeX it says, for example, '(preloaded format=plain 1982.11.19)', showing the year, month, and day that the format file was created. We have *format_ident* ≡ 0 before TeX's tables are loaded.

⟨ Global variables 13 ⟩ +≡
  static str_number *format_ident*, *frozen_format_ident*;

1300.   ⟨ Set initial values of key variables 21 ⟩ +≡
  format_ident ← *frozen_format_ident* ← 0;

1301.   We keep a copy of the initial value, be able to test for it later.

⟨ Initialize table entries (done by INITEX only) 164 ⟩ +≡
  format_ident ← *frozen_format_ident* ← *s_no*("␣(INITEX)");

1302.   ⟨ Declare action procedures for use by *main_control* 1043 ⟩ +≡
#**ifdef** INIT
  static void *store_fmt_file*(**void**)
  { **int** *j*, *k*, *l*;   ▷ all-purpose indices ◁
    int *p*, *q*;   ▷ all-purpose pointers ◁
    int *x*;   ▷ something to dump ◁
    four_quarters *w*;   ▷ four ASCII codes ◁

    ⟨ If dumping is not allowed, abort 1304 ⟩;
    ⟨ Create the *format_ident*, open the format file, and inform the user that dumping has begun 1328 ⟩;
    eqtb[*dimen_base* + *hsize_code*].*i* ← *hhsize*; *eqtb*[*dimen_base* + *vsize_code*].*i* ← *hvsize*;
    ⟨ Dump constants for consistency check 1307 ⟩;
    ⟨ Dump the string pool 1309 ⟩;
    ⟨ Dump the dynamic memory 1311 ⟩;
    ⟨ Dump the table of equivalents 1313 ⟩;
    ⟨ Dump the font information 1320 ⟩;
    ⟨ Dump the hyphenation tables 1324 ⟩;
    ⟨ Dump a couple more things and the closing check word 1326 ⟩;
    ⟨ Close the format file 1329 ⟩;
    eqtb[*dimen_base* + *hsize_code*].*i* ← 0; *eqtb*[*dimen_base* + *vsize_code*].*i* ← 0;
  }
#**endif**

1303. Corresponding to the procedure that dumps a format file, we have a function that reads one in. The function returns *false* if the dumped format is incompatible with the present TEX table sizes, etc.

#**define** *too_small*(X)
⟨ *wake_up_terminal*; *wterm_ln*("−−−!␣Must␣increase␣the␣%s", X); **goto** *bad_fmt*;
⟩

⟨ Declare the function called *open_fmt_file* 524 ⟩

　static bool *load_fmt_file*(**void**)
　{ **int** *j, k*;   ▷ all-purpose indices ◁
　　int *p, q*;   ▷ all-purpose pointers ◁
　　int *x*;   ▷ something undumped ◁
　　four_quarters *w*;   ▷ four ASCII codes ◁

　　⟨ Undump constants for consistency check 1308 ⟩;

　　⟨ Undump the font information 1321 ⟩;
　　⟨ Undump the hyphenation tables 1325 ⟩;
　　⟨ Undump a couple more things and the closing check word 1327 ⟩;
　　return *true*;   ▷ it worked! ◁
　bad_fmt: *wake_up_terminal*; *wterm_ln*("(Fatal␣format␣file␣error;␣I'm␣stymied)"); **return** *false*;
　}

1304. The user is not allowed to dump a format file unless *save_ptr* ≡ 0. This condition implies that *cur_level* ≡ *level_one*, hence the *xeq_level* array is constant and it need not be dumped.

⟨ If dumping is not allowed, abort 1304 ⟩ ≡
　if (*save_ptr* ≠ 0) { *print_err*("You␣can't␣dump␣inside␣a␣group");
　　help1("'{...\\dump}'␣is␣a␣no-no."); *succumb*;
　}

This code is used in section 1302.

1305. Format files consist of **memory_word** items, and we use the following macros to dump words of different types:

#**define** *dump_wd*(A)
　{ *fmt_file.d* ← A; *put*(*fmt_file*); }
#**define** *dump_int*(A)
　{ *fmt_file.d.i* ← A; *put*(*fmt_file*); }
#**define** *dump_hh*(A)
　{ *fmt_file.d.hh* ← A; *put*(*fmt_file*); }
#**define** *dump_qqqq*(A)
　{ *fmt_file.d.qqqq* ← A; *put*(*fmt_file*); }

⟨ Global variables 13 ⟩ +≡
　static word_file *fmt_file*;   ▷ for input or output of format information ◁

1306. The inverse macros are slightly more complicated, since we need to check the range of the values we are reading in. We say '$undump(a)(b)(x)$' to read an integer value x that is supposed to be in the range $a \leq x \leq b$. System error messages should be suppressed when undumping.

#**define** $undump\_wd(A)$
        $\{ get(fmt\_file); A \leftarrow fmt\_file.d; \}$
#**define** $undump\_int(A)$
        $\{ get(fmt\_file); A \leftarrow fmt\_file.d.i; \}$
#**define** $undump\_hh(A)$
        $\{ get(fmt\_file); A \leftarrow fmt\_file.d.hh; \}$
#**define** $undump\_qqqq(A)$
        $\{ get(fmt\_file); A \leftarrow fmt\_file.d.qqqq; \}$
#**define** $undump(A, B, C)$
        $\{ undump\_int(x);$
           if $((x < A) \vee (x > B))$ **goto** $bad\_fmt;$ **else** $C \leftarrow x; \}$
#**define** $undump\_size(A, B, C, D)$
        $\{ undump\_int(x);$
           if $(x < A)$ **goto** $bad\_fmt;$
           if $(x > B)$ $too\_small(C)$ **else** $D \leftarrow x; \}$

1307. The next few sections of the program should make it clear how we use the dump/undump macros.

⟨ Dump constants for consistency check 1307 ⟩ ≡
  $dump\_int(0);$
  ⟨ Dump the ε-TEX state 1386 ⟩
  ⟨ Dump the PRoTE state 1545 ⟩

$w\_close(\&fmt\_file)$

This code is used in section 1302.

1330.   The main program.   This is it: the part of TEX that executes all those procedures we have written.

Well—almost. Let's leave space for a few more routines that we may have forgotten.

⟨ Last-minute procedures 1333 ⟩

1331.   We have noted that there are two versions of TEX82. One, called `INITEX`, has to be run first; it initializes everything from scratch, without reading a format file, and it has the capability of dumping a format file. The other one is called 'VIRTEX'; it is a "virgin" program that needs to input a format file in order to get started. `VIRTEX` typically has more memory capacity than `INITEX`, because it does not need the space consumed by the auxiliary hyphenation tables and the numerous calls on *primitive*, etc.

The `VIRTEX` program cannot read a format file instantaneously, of course; the best implementations therefore allow for production versions of TEX that not only avoid the loading routine for Pascal object code, they also have a format file pre-loaded. This is impossible to do if we stick to standard Pascal; but there is a simple way to fool many systems into avoiding the initialization, as follows: (1) We declare a global integer variable called *ready_already*. The probability is negligible that this variable holds any particular value like 314159 when `VIRTEX` is first loaded.   (2) After we have read in a format file and initialized everything, we set *ready_already* ← 314159.   (3) Soon `VIRTEX` will print '∗', waiting for more input; and at this point we interrupt the program and save its core image in some form that the operating system can reload speedily.   (4) When that core image is activated, the program starts again at the beginning; but now *ready_already* ≡ 314159 and all the other global variables have their initial values too. The former chastity has vanished!

In other words, if we allow ourselves to test the condition *ready_already* ≡ 314159, before *ready_already* has been assigned a value, we can avoid the lengthy initialization. Dirty tricks rarely pay off so handsomely.

On systems that allow such preloading, the standard program called `TeX` should be the one that has `plain` format preloaded, since that agrees with *The TEXbook*. Other versions, e.g., `AmSTeX`, should also be provided for commonly used formats.

⟨ Global variables 13 ⟩ +≡
  static int *ready_already*;   ▷ a sacrifice of purity for economy ◁

1332.   Now this is really it: TₑX starts and ends here.

The initial test involving *ready_already* should be deleted if the Pascal runtime system is smart enough to detect such a "mistake."

> **int** *main*(**int** *argc*, **char** *∗argv*[])
> {   ▷ *start_here* ◁
>   *hlog* ← *stderr*; *main_init*(*argc*, *argv*);   ▷ TₑX Live ◁
>   *history* ← *fatal_error_stop*;   ▷ in case we quit during initialization ◁
>   *t_open_out*;   ▷ open the terminal for output ◁
>   **if** (*ready_already* ≡ 314159) **goto** *start_of_TEX*;
>   ⟨Check the "constant" values for consistency 14⟩
>   **if** (*bad* > 0) {
>   *wterm_ln*("Ouch---my␣internal␣constants␣have␣been␣clobbered!""---case␣%d", *bad*); *exit*(0);
>   }
>   *get_strings_started*(); *initialize*();   ▷ set global variables to their starting values ◁
> **#ifdef** INIT
>   **if** (*iniversion*)   ▷ TₑX Live ◁
>   {
>   *init_prim*();   ▷ call *primitive* for each primitive ◁
>   *init_str_ptr* ← *str_ptr*; *init_pool_ptr* ← *pool_ptr*; *fix_date_and_time*();
>   }
> **#endif**
>   *ready_already* ← 314159;
> *start_of_TEX*: ⟨Initialize the output routines 55⟩;
>   ⟨Get the first line of input and prepare to start 1337⟩;
>   *history* ← *spotless*;   ▷ ready to go! ◁
>   *hhsize* ← *hsize*; *hvsize* ← *vsize*; *hout_allocate*();
>   *main_control*();   ▷ come to life ◁
>   *final_cleanup*();   ▷ prepare for death ◁
>   *close_files_and_terminate*(); *ready_already* ← 0; **return** 0;
> }

1333.   Here we do whatever is needed to complete TeX's job gracefully on the local operating system. The code here might come into play after a fatal error; it must therefore consist entirely of "safe" operations that cannot produce error messages. For example, it would be a mistake to call *str_room* or *make_string* at this time, because a call on *overflow* might lead to an infinite loop. (Actually there's one way to get error messages, via *prepare_mag*; but that can't cause infinite recursion.)

If *final_cleanup* is bypassed, this program doesn't bother to close the input files that may still be open.

⟨ Last-minute procedures 1333 ⟩ ≡

1338.   Debugging.   Once TEX is working, you should be able to diagnose most errors with the `\show`
commands and other diagnostic features. But for the initial stages of debugging, and for the revelation of
really deep mysteries, you can compile TEX with a few more aids, including the Pascal runtime checks and
its debugger. An additional routine called *debug_help* will also come into play when you type 'D' after an
error message; *debug_help* also occurs just before a fatal error causes TEX to succumb.

  The interface to *debug_help* is primitive, but it is good enough when used with a Pascal debugger that
allows you to set breakpoints and to read variables and change their values. After getting the prompt
'`debug #`', you type either a negative number (this exits *debug_help*), or zero (this goes to a location where
you can set a breakpoint, thereby entering into dialog with the Pascal debugger), or a positive number m
followed by an argument n. The meaning of m and n will be clear from the program below. (If $m \equiv 13$,
there is an additional argument, l.)

⟨ Last-minute procedures 1333 ⟩ +≡

This code is used in section 1338.

1340.   Extensions.   The program above includes a bunch of "hooks" that allow further capabilities to be added without upsetting TEX's basic structure. Most of these hooks are concerned with "whatsit" nodes, which are intended to be used for special purposes; whenever a new extension to TEX involves a new kind of whatsit node, a corresponding change needs to be made to the routines below that deal with such nodes, but it will usually be unnecessary to make many changes to the other parts of this program.

In order to demonstrate how extensions can be made, we shall treat '\write', '\openout', '\closeout', '\immediate', '\special', and '\setlanguage' as if they were extensions. These commands are actually primitives of TEX, and they should appear in all implementations of the system; but let's try to imagine that they aren't. Then the program below illustrates how a person could add them.

Sometimes, of course, an extension will require changes to TEX itself; no system of hooks could be complete enough for all conceivable extensions. The features associated with '\write' are almost all confined to the following paragraphs, but there are small parts of the *print_ln* and *print_char* procedures that were introduced specifically to \write characters. Furthermore one of the token lists recognized by the scanner is a *write_text*; and there are a few other miscellaneous places where we have already provided for some aspect of \write. The goal of a TEX extender should be to minimize alterations to the standard parts of the program, and to avoid them completely if possible. He or she should also be quite sure that there's no easy way to accomplish the desired goals with the standard features that TEX already has. "Think thrice before extending," because that may save a lot of work, and it will also keep incompatible extensions of TEX from proliferating.

1341. First let's consider the format of whatsit nodes that are used to represent the data associated with
\write and its relatives. Recall that a whatsit has *type* ≡ *whatsit_node*, and the *subtype* is supposed
to distinguish different kinds of whatsits. Each node occupies two or more words; the exact number is
immaterial, as long as it is readily determined from the *subtype* or other data.

   We shall introduce five *subtype* values here, corresponding to the control sequences \openout, \write,
\closeout, \special, and \setlanguage. The second word of I/O whatsits has a *write_stream* field that
identifies the write-stream number (0 to 15, or 16 for out-of-range and positive, or 17 for out-of-range and
negative). In the case of \write and \special, there is also a field that points to the reference count of a
token list that should be sent. In the case of \openout, we need three words and three auxiliary subfields
to hold the string numbers for name, area, and extension.

See also sections 1350 and 1351.

This code is used in section 1348.

1350. Here is a subroutine that creates a whatsit node having a given *subtype* and a given number of words. It initializes only the first word of the whatsit, and appends it to the current list.

⟨Declare procedures needed in *do_extension* 1349⟩ +≡

 static void *new_whatsit*(**small_number** *s*, **small_number** *w*)

 { **pointer** *p*;   ▷ the new node ◁

  p ← *get_node*(*w*); *type*(*p*) ← *whatsit_node*; *subtype*(*p*) ← *s*; *link*(*tail*) ← *p*; *tail* ← *p*;

 }

1351. The next subroutine uses *cur_chr* to decide what sort of whatsit is involved, and also inserts a *write_stream* number.

⟨Declare procedures needed in *do_extension* 1349⟩ +≡

 static void *new_write_whatsit*(**small_number** *w*)

 { *new_whatsit*(*cur_chr*, *w*);

  if (*w* ≠ *write_node_size*) *scan_four_bit_int*( );

  else { *scan_int*( );

   if (*cur_val* < 0) *cur_val* ← 17;

   else if (*cur_val* > 15) *cur_val* ← 16;

  }

  write_stream(*tail*) ← *cur_val*;

 }

1352.   ⟨Implement \openout 1352⟩ ≡
  { *new_write_whatsit*(*open_node_size*); *scan_optional_equals*( ); *scan_file_name*( );
    open_name(*tail*) ← *cur_name*; *open_area*(*tail*) ← *cur_area*; *open_ext*(*tail*) ← *cur_ext*;
  }

This code is used in section 1348.

1353.   When '\write 12{...}' appears, we scan the token list '{...}' without expanding its macros; the
macros will be expanded later when this token list is rescanned.

⟨Implement \write 1353⟩ ≡
  { *k* ← *cur_cs*; *new_write_whatsit*(*write_node_size*);
    cur_cs ← *k*; *p* ← *scan_toks*(*false*, *false*); *write_tokens*(*tail*) ← *def_ref*;
  }

This code is used in section 1348.

1354.   ⟨Implement \closeout 1354⟩ ≡
  { *new_write_whatsit*(*write_node_size*); *write_tokens*(*tail*) ← *null*;
  }

This code is used in section 1348.

1355.   When '\special{...}' appears, we expand the macros in the token list as in \xdef and \mark.
When marked with shipout, we keep tokens unexpanded for now.

⟨Implement \special 1355⟩ ≡
  { **if** (*scan_keyword*("shipout")) { *new_whatsit*(*latespecial_node*, *write_node_size*);
      write_stream(*tail*) ← *null*; *p* ← *scan_toks*(*false*, *false*); *write_tokens*(*tail*) ← *def_ref*;
    }
    else { *new_whatsit*(*special_node*, *write_node_size*); *write_stream*(*tail*) ← *null*;
      p ← *scan_toks*(*false*, *true*); *write_tokens*(*tail*) ← *def_ref*;
    }
  }

This code is used in section 1348.

1356.   Each new type of node that appears in our data structure must be capable of being displayed, copied, destroyed, and so on. The routines that we need for write-oriented whatsits are somewhat like those for mark nodes; other extensions might, of course, involve more subtlety here.

⟨ Basic printing procedures 56 ⟩ +≡

  out_what(*p*)

This code is used in section 622.

1369.   After all this preliminary shuffling, we come finally to the routines that actually send out the
requested data. Let's do \special first (it's easier).

⟨Declare procedures needed in *hlist_out*, *vlist_out* 1369⟩ ≡
  static void *special_out*(**pointer** *p*)
  { **pointer** *q*, *r*;   ▷ temporary variables for list manipulation ◁
    int *old_mode*;   ▷ saved *mode* ◁
    if (*subtype*(*p*) ≡ *latespecial_node*) {
       ⟨Expand macros in the token list and make *link*(*def_ref*) point to the result 1372⟩;
       write_tokens(*p*) ← *def_ref*;
    }
  }

See also sections 1371 and 1374.

This code is used in section 619.

1370.   To write a token list, we must run it through TeX's scanner, expanding macros and `\the` and `\number`, etc. This might cause runaways, if a delimited macro parameter isn't matched, and runaways would be extremely confusing since we are calling on TeX's scanner in the middle of a `\shipout` command. Therefore we will put a dummy control sequence as a "stopper," right after the token list. This control sequence is artificially defined to be `\outer`.

⟨Initialize table entries (done by INITEX only) 164⟩ +≡
    $text(end\_write) \leftarrow s\_no(\texttt{"endwrite"})$; $eq\_level(end\_write) \leftarrow level\_one$;
    $eq\_type(end\_write) \leftarrow outer\_call$; $equiv(end\_write) \leftarrow null$;

1371.   ⟨Declare procedures needed in *hlist_out*, *vlist_out* 1369⟩ +≡
  static void $write\_out(\textbf{pointer } p)$
  { **int** $old\_setting$;   ▷ holds print *selector* ◁
    int old_mode;   ▷ saved *mode* ◁
    small_number j;   ▷ write stream number ◁
    pointer q, r;   ▷ temporary variables for list manipulation ◁
    ⟨Expand macros in the token list and make $link(def\_ref)$ point to the result 1372⟩;
    $old\_setting \leftarrow selector$; $j \leftarrow write\_stream(p)$;
    if $(write\_open[j])$ $selector \leftarrow j$;
    else {   ▷ write to the terminal if file isn't open ◁
      if $((j \equiv 17) \wedge (selector \equiv term\_and\_log))$ $selector \leftarrow log\_only$;
      $print\_nl(\texttt{""})$;
    }
    $token\_show(def\_ref)$; $print\_ln(\,)$; $flush\_list(def\_ref)$; $selector \leftarrow old\_setting$;
  }

1372.   The final line of this routine is slightly subtle; at least, the author didn't think about it until getting burnt! There is a used-up token list on the stack, namely the one that contained *end_write_token*. (We insert this artificial '`\endwrite`' to prevent runaways, as explained above.) If it were not removed, and if there were numerous writes on a single page, the stack would overflow.

#define end_write_token $cs\_token\_flag + end\_write$

⟨Expand macros in the token list and make $link(def\_ref)$ point to the result 1372⟩ ≡
  $q \leftarrow get\_avail(\,)$; $info(q) \leftarrow right\_brace\_token + \texttt{'}\}\texttt{'}$;
  $r \leftarrow get\_avail(\,)$; $link(q) \leftarrow r$; $info(r) \leftarrow end\_write\_token$; $ins\_list(q)$;
  $begin\_token\_list(write\_tokens(p), write\_text)$;
  $q \leftarrow get\_avail(\,)$; $info(q) \leftarrow left\_brace\_token + \texttt{'}\{\texttt{'}$; $ins\_list(q)$;
    ▷ now we're ready to scan '{⟨token list⟩} \endwrite' ◁
  $old\_mode \leftarrow mode$; $mode \leftarrow 0$;   ▷ disable `\prevdepth`, `\spacefactor`, `\lastskip`, `\prevgraf` ◁
  $cur\_cs \leftarrow write\_loc$; $q \leftarrow scan\_toks(false, true)$;   ▷ expand macros, etc. ◁
  $get\_token(\,)$; **if** $(cur\_tok \neq end\_write\_token)$ ⟨Recover from an unbalanced write command 1373⟩;
  $mode \leftarrow old\_mode$; $end\_token\_list(\,)$ ▷ conserve stack space ◁
This code is used in sections 1369 and 1371.

1373.   ⟨Recover from an unbalanced write command 1373⟩ ≡
  { $print\_err(\texttt{"Unbalanced\_write\_command"})$;
    $help2(\texttt{"On\_this\_page\_there's\_a\_}\backslash\backslash\texttt{write\_with\_fewer\_real\_\{'s\_than\_\}'s."}$,

    do $get\_token(\,)$; **while** $(\neg(cur\_tok \equiv end\_write\_token))$;
  }
This code is used in section 1372.

1374. The *out_what* procedure takes care of outputting whatsit nodes for *vlist_out* and *hlist_out*.

⟨ Declare procedures needed in *hlist_out*, *vlist_out* 1369 ⟩ +≡
⟨ Declare procedures needed in *out_what* 1687 ⟩
 static void *out_what*(**pointer** *p*)
 { **small_number** *j*; ▷ write stream number ◁

  switch (*subtype*(*p*)) {
  case *open_node*: **case** *write_node*: **case** *close_node*:
   ⟨ Do some work that has been queued up for \write 1375 ⟩ **break**;
  case *special_node*: **case** *latespecial_node*: *special_out*(*p*); **break**;
  case *language_node*: **case** *save_pos_code*: *do_nothing*; **break**;
  default: *confusion*("ext4");
  }
 }

1375. We don't implement \write inside of leaders. (The reason is that the number of times a leader box appears might be different in different implementations, due to machine-dependent rounding in the glue calculations.)

⟨ Do some work that has been queued up for \write 1375 ⟩ ≡
 if (¬*doing_leaders*) { *j* ← *write_stream*(*p*);
  if (*subtype*(*p*) ≡ *write_node*) *write_out*(*p*);
  else { **if** (*write_open*[*j*]) *a_close*(&*write_file*[*j*]);
   if (*subtype*(*p*) ≡ *close_node*) *write_open*[*j*] ← *false*;
   else if (*j* < 16) { *cur_name* ← *open_name*(*p*); *cur_area* ← *open_area*(*p*); *cur_ext* ← *open_ext*(*p*);
    pack_cur_name(".tex");
    while (¬*a_open_out*(&*write_file*[*j*])) *prompt_file_name*("output␣file␣name", ".tex");
    write_open[*j*] ← *true*;
   }
  }
 }
This code is used in section 1374.

1376. The presence of '\immediate' causes the *do_extension* procedure to descend to one level of recursion. Nothing happens unless \immediate is followed by '\openout', '\write', or '\closeout'.

⟨ Implement \immediate 1376 ⟩ ≡
 { *get_x_token*();
  if ((*cur_cmd* ≡ *extension*) ∧ (*cur_chr* ≤ *close_node*)) { *p* ← *tail*; *do_extension*();
    ▷ append a whatsit node ◁
   out_what(*tail*); ▷ do the action immediately ◁
   flush_node_list(*tail*); *tail* ← *p*; *link*(*p*) ← *null*;
  }
  else *back_input*();
 }
This code is used in section 1348.

1377.   The `\language` extension is somewhat different. We need a subroutine that comes into play when a character of a non-*clang* language is being appended to the current paragraph.

⟨ Declare action procedures for use by *main_control* 1043 ⟩ +≡

  static void *fix_language* (**void**)
  { **ASCII_code** *l*;   ▷ the new current language ◁

    if (*language* ≤ 0) *l* ← 0;
    else if (*language* > 255) *l* ← 0;
    else *l* ← *language* ;
    if (*l* ≠ *clang*) { *new_whatsit* (*language_node* , *small_node_size*); *what_lang* (*tail*) ← *l*; *clang* ← *l*;
      what_lhm (*tail*) ← *norm_min* (*left_hyphen_min*); *what_rhm* (*tail*) ← *norm_min* (*right_hyphen_min*);
    }
  }

1378.   ⟨ Implement `\setlanguage` 1378 ⟩ ≡
  if (*abs* (*mode*) ≠ *hmode*) *report_illegal_case* ( );
  else { *new_whatsit* (*language_node* , *small_node_size*); *scan_int* ( );
    if (*cur_val* ≤ 0) *clang* ← 0;
    else if (*cur_val* > 255) *clang* ← 0;
    else *clang* ← *cur_val* ;
    what_lang (*tail*) ← *clang* ; *what_lhm* (*tail*) ← *norm_min* (*left_hyphen_min*);
    what_rhm (*tail*) ← *norm_min* (*right_hyphen_min*);
  }
This code is used in section 1348.

1379.   ⟨ Finish the extensions 1379 ⟩ ≡
  for (*k* ← 0; *k* ≤ 15; *k*++) **if** (*write_open* [*k*]) *a_close* (&*write_file* [*k*])
This code is used in section 1333.

1380. The extended features of ε-T_EX. The program has three modes of operation: (1) In T_EX compatibility mode it fully deserves the name T_EX and there are neither extended features nor additional primitive commands. There are, however, a few modifications that would be legitimate in any implementation of T_EX such as, e.g., preventing inadequate results of the glue to DVI unit conversion during *ship_out*. (2) In extended mode there are additional primitive commands and the extended features of ε-T_EX are available. (3) In PROTE mode there are supplementary primitive commands that will be discussed in the section below.

The distinction between these three modes of operation initially takes place when a 'virgin' eINITEX starts without reading a format file. Later on the values of all ε-T_EX state variables are inherited when eVIRTEX (or eINITEX) reads a format file.

The code below is designed to work for cases where '#**ifdef** INIT . . . #**endif**' is a run-time switch.

$\langle$ Enable ε-T_EX and furthermore Prote, if requested 1380 $\rangle \equiv$
#**ifdef** INIT

1381.   The ε-T_EX features available in extended mode are grouped into two categories: (1) Some of them are permanently enabled and have no semantic effect as long as none of the additional primitives are executed. (2) The remaining ε-T_EX features are optional and can be individually enabled and disabled. For each optional feature there is an ε-T_EX state variable named \...**state**; the feature is enabled, resp. disabled by assigning a positive, resp. non-positive value to that integer.

        if ((*cur_cmd* ≥ *call*) ∧ (*cur_cmd* < *end_template*))
            if (*info*(*link*(*cur_chr*)) ≡ *protected_token*) **return**;
        expand( );
        }
    }

1457. A group entered (or a conditional started) in one file may end in a different file. Such slight anomalies, although perfectly legitimate, may cause errors that are difficult to locate. In order to be able to give a warning message when such anomalies occur, ε-TEX uses the *grp_stack* and *if_stack* arrays to record the initial *cur_boundary* and *cond_ptr* values for each input file.

⟨Global variables 13⟩ +≡
    static save_pointer *grp_stack*[*max_in_open* + 1];   ▷ initial *cur_boundary* ◁
    static pointer *if_stack*[*max_in_open* + 1];   ▷ initial *cond_ptr* ◁

1458. When a group ends that was apparently entered in a different input file, the *group_warning* procedure is invoked in order to update the *grp_stack*. If moreover \tracingnesting is positive we want to give a warning message. The situation is, however, somewhat complicated by two facts: (1) There may be *grp_stack* elements without a corresponding \input file or \scantokens pseudo file (e.g., error insertions from the terminal); and (2) the relevant information is recorded in the *name_field* of the *input_stack* only loosely synchronized with the *in_open* variable indexing *grp_stack*.

⟨Declare ε-TEX procedures for tracing and input 284⟩ +≡
    static void *group_warning*(**void**)
    { **int** *i*;   ▷ index into *grp_stack* ◁
        bool *w*;   ▷ do we need a warning? ◁

        base_ptr ← *input_ptr*; *input_stack*[*base_ptr*] ← *cur_input*;   ▷ store current state ◁
        i ← *in_open*; *w* ← *false*;
        while ((*grp_stack*[*i*] ≡ *cur_boundary*) ∧ (*i* > 0)) {
            ⟨Set variable *w* to indicate if this case should be reported 1459⟩;
            grp_stack[*i*] ← *save_index*(*save_ptr*); *decr*(*i*);
        }
        if (*w*) { *print_nl*("Warning:␣end␣of␣"); *print_group*(*true*); *print*("␣of␣a␣different␣file");
            print_ln( );
            if (*tracing_nesting* > 1) *show_context*( );
            if (*history* ≡ *spotless*) *history* ← *warning_issued*;
        }
    }

1459. This code scans the input stack in order to determine the type of the current input file.

⟨Set variable *w* to indicate if this case should be reported 1459⟩ ≡
    if (*tracing_nesting* > 0) { **while** ((*input_stack*[*base_ptr*].*state_field* ≡ *token_list*) ∨
            (*input_stack*[*base_ptr*].*index_field* > *i*)) *decr*(*base_ptr*);
        if (*input_stack*[*base_ptr*].*name_field* > 17) *w* ← *true*;
    }

This code is used in sections 1458 and 1460.

1460.   When a conditional ends that was apparently started in a different input file, the *if_warning*
procedure is invoked in order to update the *if_stack*. If moreover \tracingnesting is positive we want
to give a warning message (with the same complications as above).

$\langle$ Declare ε-TEX procedures for tracing and input 284 $\rangle$ $+\equiv$
    static void *if_warning*(**void**)
  { **int** *i*;   ▷ index into *if_stack* ◁
    bool *w*;   ▷ do we need a warning? ◁

    else if $(y \geq -max\_answer - x)$ $a \leftarrow x + y$; **else** $num\_error(a)$;
    return a;
  $\}$

See also sections 1481 and 1483.

This code is used in section 1466.

1478.   We know that $stretch\_order(e) > normal$ implies $stretch(e) \neq 0$ and $shrink\_order(e) > normal$ implies $shrink(e) \neq 0$.

$\langle$ Compute the sum or difference of two glue specs 1478 $\rangle \equiv$
  $\{$ $width(e) \leftarrow expr\_a(width(e), width(t))$;
    if $(stretch\_order(e) \equiv stretch\_order(t))$ $stretch(e) \leftarrow expr\_a(stretch(e), stretch(t))$;
    else if $((stretch\_order(e) < stretch\_order(t)) \wedge (stretch(t) \neq 0))$ $\{$ $stretch(e) \leftarrow stretch(t)$;
      $stretch\_order(e) \leftarrow stretch\_order(t)$;
    $\}$
    if $(shrink\_order(e) \equiv shrink\_order(t))$ $shrink(e) \leftarrow expr\_a(shrink(e), shrink(t))$;
    else if $((shrink\_order(e) < shrink\_order(t)) \wedge (shrink(t) \neq 0))$ $\{$ $shrink(e) \leftarrow shrink(t)$;
      $shrink\_order(e) \leftarrow shrink\_order(t)$;
    $\}$
    $delete\_glue\_ref(t)$; $normalize\_glue(e)$;
  $\}$

This code is used in section 1476.

1479.   If a multiplication is followed by a division, the two operations are combined into a 'scaling' operation. Otherwise the term t is multiplied by the factor f.

#define $expr\_m(A)$ $A \leftarrow nx\_plus\_y(A, f, 0)$

$\langle$ Cases for evaluation of the current term 1475 $\rangle$ +$\equiv$
case $expr\_mult$:
  if $(o \equiv expr\_div)$ $\{$ $n \leftarrow f$; $o \leftarrow expr\_scale$;
  $\}$
  else if $(l \equiv int\_val)$ $t \leftarrow mult\_integers(t, f)$;
  else if $(l \equiv dimen\_val)$ $expr\_m(t)$;
  else $\{$ $expr\_m(width(t))$; $expr\_m(stretch(t))$; $expr\_m(shrink(t))$;
  $\}$ **break**;

1480.   Here we divide the term t by the factor f.

#define $expr\_d(A)$ $A \leftarrow quotient(A, f)$

$\langle$ Cases for evaluation of the current term 1475 $\rangle$ +$\equiv$
case $expr\_div$:
  if $(l < glue\_val)$ $expr\_d(t)$;
  else $\{$ $expr\_d(width(t))$; $expr\_d(stretch(t))$; $expr\_d(shrink(t))$;
  $\}$ **break**;

1481.   The function $quotient(n, d)$ computes the rounded quotient $q = \lfloor n/d + \frac{1}{2} \rfloor$, when n and d are positive.

$\langle$ Declare subprocedures for $scan\_expr$ 1477 $\rangle$ +≡

  static int $quotient(\textbf{int } n, \textbf{int } d)$

  { **bool** $negative$;   ▷ should the answer be negated? ◁

    int a;   ▷ the answer ◁

    if $(d \equiv 0)$ $num\_error(a)$

    else { **if** $(d > 0)$ $negative \leftarrow false$;

      else { $negate(d)$; $negative \leftarrow true$;

      }

      if $(n < 0)$ { $negate(n)$; $negative \leftarrow \neg negative$;

      }

      $a \leftarrow n/d$; $n \leftarrow n - a * d$; $d \leftarrow n - d$;   ▷ avoid certain compiler optimizations! ◁

      if $(d + n \geq 0)$ $incr(a)$;

      if $(negative)$ $negate(a)$;

    }

    return a;

  }

1482.   Here the term t is multiplied by the quotient n/f.

#define $expr\_s(A)$ $A \leftarrow fract(A, n, f, max\_dimen)$

$\langle$ Cases for evaluation of the current term 1475 $\rangle$ +≡

case $expr\_scale$:

  if $(l \equiv int\_val)$ $t \leftarrow fract(t, n, f, infinity)$;

  else if $(l \equiv dimen\_val)$ $expr\_s(t)$;

  else { $expr\_s(width(t))$; $expr\_s(stretch(t))$; $expr\_s(shrink(t))$;

    }

1483.   Finally, the function $fract(x, n, d, max\_answer)$ computes the integer $q = \lfloor xn/d + \frac{1}{2} \rfloor$, when x, n, and d are positive and the result does not exceed max_answer. We can't use floating point arithmetic since the routine must produce identical results in all cases; and it would be too dangerous to multiply by n and then divide by d, in separate operations, since overflow might well occur. Hence this subroutine simulates double precision arithmetic, somewhat analogous to METAFONT's $make\_fraction$ and $take\_fraction$ routines.

⟨ Declare subprocedures for $scan\_expr$ 1477 ⟩ +≡
  static int $fract$(**int** x, **int** n, **int** d, **int** max_answer)
  { **bool** $negative$;   ▷ should the answer be negated? ◁

1493. ε-TEX (in extended mode) supports 32768 (i.e., 2^{15}) count, dimen, skip, muskip, box, and token registers. As in TEX the first 256 registers of each kind are realized as arrays in the table of equivalents; the additional registers are realized as tree structures built from variable-size nodes with individual registers existing only when needed. Default values are used for nonexistent registers: zero for count and dimen values, *zero_glue* for glue (skip and muskip) values, void for boxes, and *null* for token lists (and current marks discussed below).

Similarly there are 32768 mark classes; the command \marks*n* creates a mark node for a given mark class $0 \le n \le 32767$ (where \marks0 is synonymous to \mark). The page builder (actually the *fire_up* routine) and the *vsplit* routine maintain the current values of *top_mark*, *first_mark*, *bot_mark*, *split_first_mark*, and *split_bot_mark* for each mark class. They are accessed as \topmarks*n* etc., and \topmarks0 is again synonymous to \topmark. As in TEX the five current marks for mark class zero are realized as *cur_mark* array. The additional current marks are again realized as tree structure with individual mark classes existing only when needed.

1499.   There are seven almost identical doubly linked trees, one for the sparse array of the up to 32512 additional registers of each kind and one for the sparse array of the up to 32767 additional mark classes. The root of each such tree, if it exists, is an index node containing 16 pointers to subtrees for 4096 consecutive array elements. Similar index nodes are the starting points for all nonempty subtrees for 4096, 256, and 16 consecutive array elements. These four levels of index nodes are followed by a fifth level with nodes for the individual array elements.

Each index node is nine words long. The pointers to the 16 possible subtrees or are kept in the *info* and *link* fields of the last eight words. (It would be both elegant and efficient to declare them as array, unfortunately Pascal doesn't allow this.)

The fields in the first word of each index node and in the nodes for the array elements are closely related. The *link* field points to the next lower index node and the *sa_index* field contains four bits (one hexadecimal digit) of the register number or mark class. For the lowest index node the *link* field is *null* and the *sa_index* field indicates the type of quantity (*int_val*, *dimen_val*, *glue_val*, *mu_val*, *box_val*, *tok_val*, or *mark_val*). The *sa_used* field in the index nodes counts how many of the 16 pointers are non-null.

The *sa_index* field in the nodes for array elements contains the four bits plus 16 times the type. Therefore such a node represents a count or dimen register if and only if $sa\_index < dimen\_val\_limit$; it represents a skip or muskip register if and only if $dimen\_val\_limit \leq sa\_index < mu\_val\_limit$; it represents a box register if and only if $mu\_val\_limit \leq sa\_index < box\_val\_limit$; it represents a token list register if and only if $box\_val\_limit \leq sa\_index < tok\_val\_limit$; finally it represents a mark class if and only if $tok\_val\_limit \leq sa\_index$.

The *new_index* procedure creates an index node (returned in *cur_ptr*) having given contents of the *sa_index* and *link* fields.

1503.   Given a type t and a sixteen-bit number n, the *find_sa_element* procedure returns (in *cur_ptr*) a pointer to the node for the corresponding array element, or *null* when no such element exists. The third parameter w is set *true* if the element must exist, e.g., because it is about to be modified. The procedure has two main branches: one follows the existing tree structure, the other (only used when w is *true*) creates the missing nodes.

   We use macros to extract the four-bit pieces from a sixteen-bit register number or mark class and to fetch or store one of the 16 pointers from an index node.

  }

1504.   The array elements for registers are subject to grouping and have an *sa_lev* field (quite analogous to *eq_level*) instead of *sa_used*. Since saved values as well as shorthand definitions (created by e.g., \countdef) refer to the location of the respective array element, we need a reference count that is kept in the *sa_ref* field. An array element can be deleted (together with all references to it) when its *sa_ref* value is *null* and its value is the default value.

Skip, muskip, box, and token registers use two word nodes, their values are stored in the *sa_ptr* field. Count and dimen registers use three word nodes, their values are stored in the *sa_int* resp. *sa_dim* field in the third word; the *sa_ptr* field is used under the name *sa_num* to store the register number. Mark classes use four word nodes. The last three words contain the five types of current marks

#**define** *sa_lev* *sa_used*   ▷ grouping level for the current value ◁

      else $cur\_ptr \leftarrow info(cur\_ptr + (t/2) + 1)$;
  }
This code is used in section 386.

1509.   The current marks for all mark classes are maintained by the *vsplit* and *fire_up* routines and are
finally destroyed (for `INITEX` only) by the *final_cleanup* routine. Apart from updating the current marks
when mark nodes are encountered, these routines perform certain actions on all existing mark classes. The
recursive *do_marks* procedure walks through the whole tree or a subtree of existing mark class nodes and
preforms certain actions indicted by its first parameter a, the action code. The second parameter l indicates
the level of recursion (at most four); the third parameter points to a nonempty tree or subtree. The result
is *true* if the complete tree or subtree has been deleted.

    }
    if $(sa\_used(q) \equiv 0)$ { $free\_node(q, index\_node\_size)$; $q \leftarrow null$;
    }
    }
    else   ▷ q is the node for a mark class ◁
    { **switch** (a) {
    ⟨Cases for *do_marks* 1510⟩
    }   ▷ there are no other cases ◁
    if $(sa\_bot\_mark(q) \equiv null)$
      if $(sa\_split\_bot\_mark(q) \equiv null)$ { $free\_node(q, mark\_class\_node\_size)$; $q \leftarrow null$;
      }
    }
    return $(q \equiv null)$;
  }

This code is used in section 977.

1510.   At the start of the *vsplit* routine the existing *split_fist_mark* and *split_bot_mark* are discarded.

⟨Cases for *do_marks* 1510⟩ ≡
case *vsplit_init*:
  if $(sa\_split\_first\_mark(q) \neq null)$ { $delete\_token\_ref(sa\_split\_first\_mark(q))$;
    $sa\_split\_first\_mark(q) \leftarrow null$; $delete\_token\_ref(sa\_split\_bot\_mark(q))$; $sa\_split\_bot\_mark(q) \leftarrow null$;
  } **break**;

See also sections 1512, 1513, and 1515.

This code is used in section 1509.

1511.   We use again the fact that $split\_first\_mark \equiv null$ if and only if $split\_bot\_mark \equiv null$.

$\langle$ Update the current marks for $vsplit$ 1511 $\rangle \equiv$
  $\{$ $find\_sa\_element(mark\_val, mark\_class(p), true)$;
    if $(sa\_split\_first\_mark(cur\_ptr) \equiv null)$ $\{$ $sa\_split\_first\_mark(cur\_ptr) \leftarrow mark\_ptr(p)$;
      $add\_token\_ref(mark\_ptr(p))$;
    $\}$
    else $delete\_token\_ref(sa\_split\_bot\_mark(cur\_ptr))$;
    $sa\_split\_bot\_mark(cur\_ptr) \leftarrow mark\_ptr(p)$; $add\_token\_ref(mark\_ptr(p))$;
  $\}$

This code is used in section 979.

1512.   At the start of the $fire\_up$ routine the old top_mark and $first\_mark$ are discarded, whereas the old bot_mark becomes the new top_mark. An empty new top_mark token list is, however, discarded as well in order that mark class nodes can eventually be released. We use again the fact that $bot\_mark \neq null$ implies $first\_mark \neq null$; it also knows that $bot\_mark \equiv null$ implies $top\_mark \equiv first\_mark \equiv null$.

$\langle$ Cases for do_marks 1510 $\rangle + \equiv$
case $fire\_up\_init$:
  if $(sa\_bot\_mark(q) \neq null)$ $\{$ **if** $(sa\_top\_mark(q) \neq null)$ $delete\_token\_ref(sa\_top\_mark(q))$;
    $delete\_token\_ref(sa\_first\_mark(q))$; $sa\_first\_mark(q) \leftarrow null$;
    if $(link(sa\_bot\_mark(q)) \equiv null)$ ▷ an empty token list ◁
    $\{$ $delete\_token\_ref(sa\_bot\_mark(q))$; $sa\_bot\_mark(q) \leftarrow null$;
    $\}$
    else $add\_token\_ref(sa\_bot\_mark(q))$;
    $sa\_top\_mark(q) \leftarrow sa\_bot\_mark(q)$;
  $\}$ **break**;

1513. $\langle$ Cases for do_marks 1510 $\rangle + \equiv$
case $fire\_up\_done$:
  if $((sa\_top\_mark(q) \neq null) \wedge (sa\_first\_mark(q) \equiv null))$ $\{$ $sa\_first\_mark(q) \leftarrow sa\_top\_mark(q)$;
    $add\_token\_ref(sa\_top\_mark(q))$;
  $\}$ **break**;

1514. $\langle$ Update the current marks for $fire\_up$ 1514 $\rangle \equiv$
  $\{$ $find\_sa\_element(mark\_val, mark\_class(p), true)$;
    if $(sa\_first\_mark(cur\_ptr) \equiv null)$ $\{$ $sa\_first\_mark(cur\_ptr) \leftarrow mark\_ptr(p)$;
      $add\_token\_ref(mark\_ptr(p))$;
    $\}$
    if $(sa\_bot\_mark(cur\_ptr) \neq null)$ $delete\_token\_ref(sa\_bot\_mark(cur\_ptr))$;
    $sa\_bot\_mark(cur\_ptr) \leftarrow mark\_ptr(p)$; $add\_token\_ref(mark\_ptr(p))$;
  $\}$

This code is used in section 1014.

1515. Here we use the fact that the five current mark pointers in a mark class node occupy the same locations as the the first five pointers of an index node. For systems using a run-time switch to distinguish between VIRTEX and INITEX, the codewords '#**ifdef** INIT ... #**endif**' surrounding the following piece of code should be removed.

⟨Cases for do_marks 1510⟩ +≡
#**ifdef** INIT
case $destroy\_marks$:
  for $(i \leftarrow top\_mark\_code;\ i \leq split\_bot\_mark\_code;\ i{+}{+})$ { get_sa_ptr;
    if $(cur\_ptr \neq null)$ { $delete\_token\_ref(cur\_ptr)$; $put\_sa\_ptr(null)$;
    }
  }
#**endif**

1516. The command code $internal\_register$ is used for '\count', '\dimen', etc., as well as for references to sparse array elements defined by '\countdef', etc.

⟨Cases of **register** for $print\_cmd\_chr$ 1516⟩ ≡
  { **if** $((chr\_code < mem\_bot) \vee (chr\_code > lo\_mem\_stat\_max))$ $cmd \leftarrow sa\_type(chr\_code)$;
    else { $cmd \leftarrow chr\_code - mem\_bot$; $chr\_code \leftarrow null$;
    }
    if $(cmd \equiv int\_val)$ $print\_esc(\texttt{"count"})$;
    else if $(cmd \equiv dimen\_val)$ $print\_esc(\texttt{"dimen"})$;
    else if $(cmd \equiv glue\_val)$ $print\_esc(\texttt{"skip"})$;
    else $print\_esc(\texttt{"muskip"})$;
    if $(chr\_code \neq null)$ $print\_sa\_num(chr\_code)$;
  }
This code is used in section 412.

1517. Similarly the command code $toks\_register$ is used for '\toks' as well as for references to sparse array elements defined by '\toksdef'.

⟨Cases of $toks\_register$ for $print\_cmd\_chr$ 1517⟩ ≡
  { $print\_esc(\texttt{"toks"})$;
    if $(chr\_code \neq mem\_bot)$ $print\_sa\_num(chr\_code)$;
  }
This code is used in section 266.

1518. When a shorthand definition for an element of one of the sparse arrays is destroyed, we must reduce the reference count.

⟨Cases for $eq\_destroy$ 1518⟩ ≡
case $toks\_register$: **case** $internal\_register$:
  if $((equiv\_field(w) < mem\_bot) \vee (equiv\_field(w) > lo\_mem\_stat\_max))$ $delete\_sa\_ref(equiv\_field(w))$;
    break;
This code is used in section 275.

1519. The task to maintain (change, save, and restore) register values is essentially the same when the register is realized as sparse array element or entry in $eqtb$. The global variable sa_chain is the head of a linked list of entries saved at the topmost level sa_level; the lists for lowel levels are kept in special save stack entries.

⟨Global variables 13⟩ +≡
  static pointer sa_chain;   ▷ chain of saved sparse array entries ◁
  static quarterword sa_level;   ▷ group level for sa_chain ◁

1520.   ⟨ Set initial values of key variables 21 ⟩ +≡
  $sa\_chain \leftarrow null$; $sa\_level \leftarrow level\_zero$;

1521.   The individual saved items are kept in pointer or word nodes similar to those used for the array elements: a word node with value zero is, however, saved as pointer node with the otherwise impossible sa_index value tok_val_limit.

#**define** $sa\_loc(A)$ $sa\_ref(A)$ ▷ location of saved item ◁

⟨ Declare ε-TeX procedures for tracing and input 284 ⟩ +≡
  static void $sa\_save(\textbf{pointer } p)$ ▷ saves value of p ◁
  { **pointer** q;   ▷ the new save node ◁
    quarterword i;   ▷ index field of node ◁

1543.   The extended features of PROTE.   PROTE extends furthermore ε-TEX i.e. ε-TEX is thus required before adding PROTE own extensions. But if ε-TEX mode has not be enabled, the engine is still compatible with TEX with no added primitive commands and with a modification of code—from ε-TEX exclusively for now—that is sufficiently minor so that the engine still deserves the name TEX.

#**define** $Prote\_ex$ $(Prote\_mode \equiv 1)$ ▷ is this prote mode? ◁

⟨ Global variables 13 ⟩ +≡
   static int $Prote\_mode$;   ▷ to be or not to be; but an int to dump ◁

1544.   We begin in TEX compatibility mode. The state $Prote\_mode$ will be set to 1 only if activated by the supplementary '*' added to the one activating the ε-TEX extensions (in fact, this means for the user two initial '*' in a row).

⟨ Initialize table entries (done by INITEX only) 164 ⟩ +≡
   $Prote\_mode \leftarrow 0$;   ▷ initially we are in compatibility mode ◁

1545.   ⟨ Dump the PROTE state 1545 ⟩ ≡
   $dump\_int(Prote\_mode)$;
This code is used in section 1307.

1546.   ⟨ Undump the PROTE state 1546 ⟩ ≡
   $undump(0, 1, Prote\_mode)$;
This code is used in section 1308.

1547.   In order to not clobber the global scope with variables that are locally used, the initializations for PROTE, if the mode is activated, are done in a dedicated procedure. These are not part of what is dumped.

⟨ Last-minute procedures 1333 ⟩ +≡
   static void $Prote\_initialize(\textbf{void})$
   { **int** k;   ▷ all-purpose index ◁
     ⟨ PROTE initializations 1569 ⟩;
   }

1548.   There are commands and command modifiers, these command modifiers maybe encoding too a type. So we must not step on each other toes.

1549.   When we are adding primitives that deal intimately with the variables of TEX, in the $eqtb$ regions (in our case regions 5 for integers, and 6 for dimensions), the command modifier to the various `assign_*` classes is simply the address. So we have interpolated our added variables above since this is done by the way of WEB pre-processing.

1550.   For the conditional primitives, the way is straightforward.

#**define** $if\_incsname\_code$ $(eTeX\_last\_if\_test\_cmd\_mod + 1)$ ▷ '\ifincsname' ◁
#**define** $if\_primitive\_code$ $(eTeX\_last\_if\_test\_cmd\_mod + 2)$ ▷ '\ifprimitive' ◁

1551.   The *last_item* class is for secondary internal values, that can be dereferenced by `\the` but are read-only and are mainly related to the value of a current state or are such values but their assignation shall trigger an action, and we shall not hook in the `assign_*` processing.

The command modifiers for the *last_item* class were, originally, encoding too the type of the item (see m.410). But ε-TEX has added its extensions and we won't try to be smart: the type *cur_val_level* will be set by switching between contiguous ranges of values of the same type.

And we will define here all the instances of *last_item* that we add in order to keep our number assignations gathered.

#define *Prote_version_code* $(eTeX\_last\_last\_item\_cmd\_mod + 1)$ ▷ code for `\Proteversion` ◁
#define *random_seed_code* $(eTeX\_last\_last\_item\_cmd\_mod + 2)$ ▷ `\randomseed` ◁

See also sections 1596, 1602, 1614, 1618, 1622, 1626, 1655, 1662, and 1669.

This code is used in section 472.

1561.   PRⓄTE added token lists routines.
   We will, more than once, convert a general normally expanded text to a string. Due to the unfelicity of
Pascal about forward declarations of functions, we declare procedures that do their task by defining global
variables. In this case, *garbage* is used.
   link(*garbage*) will hold the pointer to the head of the token list, *info*(*garbage*) to the tail. If the two are
equals, then the list is empty. The routine making a string will take *link*(*garbage*) and put the number in
info(*garbage*).

1562.   The first procedure scan a general text (normally) expanded. The head of the reference count is
returned in *link*(*garbage*), the tail in *info*(*garbage*) and if the two are equals, the list is empty. User must
keep in mind that this has to be flushed when done with!

⟨ Forward declarations 52 ⟩ +≡
   static void *scan_general_x_text*(**void**);

1563.   ⟨ Declare PRⓄTE procedures for token lists 1563 ⟩ ≡
   static void *scan_general_x_text*(**void**)
   { **pointer** *d*;   ▷ to save *def_ref* ◁

      d ← *def_ref*; *info*(*garbage*) ← *scan_toks*(*false*, *true*); *link*(*garbage*) ← *def_ref*; *def_ref* ← *d*;
         ▷ restore whatever ◁
   }
See also section 1565.
This code is used in section 473.

1564.   The second procedure takes a token list defined in *link*(*garbage*) and converts it to a string number
that is returned in *info*(*garbage*). Neither the token list nor the string (obviously) are flushed.

⟨ Forward declarations 52 ⟩ +≡
   static void *toks_to_str*(**void**);

1565.   Here we are using *token_show* that has to take a reference count.
⟨ Declare PRⓄTE procedures for token lists 1563 ⟩ +≡
   static void *toks_to_str*(**void**)
   { **int** *old_setting*;   ▷ holds *selector* setting ◁

      old_setting ← *selector*; *selector* ← *new_string*; *token_show*(*link*(*garbage*)); *selector* ← *old_setting*;
      str_room(1);   ▷ flirting with the limit means probably truncation ◁
      info(*garbage*) ← *make_string*( );
   }

1566.   PROTE added strings routines.
The next procedure sets *name_of_file* from the string given as an argument, mimicking the *input* primitive by adding an . *tex* extension if there is none. It silently truncates if the length of the string exceeds the size of the name buffer and doesn't use *cur_area* and *cur_ext*, but *name_length* is set to the real name length (without truncating) so a test about $k \leq \textit{file_name_size}$ allows to detect the impossibility of opening the file without having to call external code. The string is not flushed: it is the responsability of the code calling the procedure to flush it if wanted.

⟨ Declare PROTE procedures for strings 1566 ⟩ ≡
  static void *str_to_name*(**str_number** *s*)
  { **int** *k*;   ▷ number of positions filled in *name_of_file* ◁
    ASCII_code *c*;   ▷ character being packed ◁
    int *j*;   ▷ index into *str_pool* ◁
    k ← 0;
    for (*j* ← *str_start*[*s*]; *j* ≤ *str_start*[*s* + 1] − 1; *j*++) { *c* ← *so*(*str_pool*[*j*]); *incr*(*k*);
      if (*k* ≤ *file_name_size*) *name_of_file*[*k*] ← *xchr*[*c*];
    }
    name_length ← *k*; *name_of_file*[*name_length* + 1] ← 0;
  }

This code is used in section 46.

1567.   Exchanging data with external routines.
In order to try to sever external handling from our core, we introduce an all purpose exchange buffer *xchg_buffer*, that will be an array of bytes (these can be interpreted as `text_char` or `ASCII_char` or `eight_bits`).

The data to be used starts at index 1 and ends at index *xchg_buffer_length*.

For the moment, this buffer must accommodate a numerical MD5 hash value, i.e. 16 bytes long; will also be used to exchange 64 bytes chunks to feed MD5 hash generation, and will have to accommodate too the maximal size of the date returned by `\creationdate` or `\filemoddate` that is 23 `text_char`. So at least 64 for now.

⟨ Global variables 13 ⟩ +≡
  static eight_bits *xchg_buffer0* [*xchg_buffer_size*], ∗**const** *xchg_buffer* ← *xchg_buffer0* − 1;
      ▷ exchange buffer for interaction with system routines ◁
  static int *xchg_buffer_length*;   ▷ last valid index in this buf; 0 means no data ◁

1568.   ⟨ Check PROTE "constant" values for consistency 1568 ⟩ ≡
  if (*xchg_buffer_size* < 64) *bad* ← 51;

This code is used in section 1380.

1569.   When there is data in the exchange buffer, the length of the data has to be set. When an external routine has consumed the data, it shall reset the length to 0.

⟨ PROTE initializations 1569 ⟩ ≡
  xchg_buffer_length ← 0;

See also sections 1575, 1636, 1651, 1673, and 1679.

This code is used in section 1547.

1570.   PROTE states.
   \shellescape depends on a pdfTEX feature, namely the ability to escape to shell. There is no such thing
in PROTE. So it expands to 0. Note: this a status primitive; it does not allow to set the status but simply
expands to a read-only integer reflecting it. In PROTE, it is always 0.

⟨ Generate all PROTE primitives 1555 ⟩ +≡
   primitive("shellescape", *last_item*, *shell_escape_code*);

**1571.   ** ⟨ Cases of *last_item* for *print_cmd_chr* 1382 ⟩ +≡
case *shell_escape_code*: *print_esc*("shellescape"); **break**;

**1572.   ** ⟨ Cases for fetching a PROTE int value 1557 ⟩ +≡
case *shell_escape_code*: *cur_val* ← 0; **break**;

1573.   PRθTE conditionals.

We add the following conditionals, that are susceptible of the same expansion rules as the other *if_test* ones.

⟨ Generate all PRθTE primitives 1555 ⟩ +≡
  primitive("ifincsname", *if_test*, *if_incsname_code*);
  primitive("ifprimitive", *if_test*, *if_primitive_code*);

1574.   ⟨ Cases of *if_test* for *print_cmd_chr* 1448 ⟩ +≡
case *if_incsname_code*: *print_esc*("ifincsname"); **break**;
case *if_primitive_code*: *print_esc*("ifprimitive"); **break**;

1575.   The conditional \ifincsname is simple since we increment a global variable *incsname_state* when we enter the \csname command and decrement it when we have reached and passed the \endcsname—a scope depth index.

⟨ PRθTE initializations 1569 ⟩ +≡
  incsname_state ← 0;

1576.   ⟨ Cases for *conditional* 1450 ⟩ +≡
case *if_incsname_code*: *b* ← (*incsname_state* > 0); **break**;

1577.   The conditional \ifprimitive is true when the following control sequence is a primitive; false otherwise. *id_lookup* can return *undefined_control_sequence* (for a control sequence not entered in the hash since *no_new_control_sequence* is *true*), but since it has the eq_type set to *undefined_cs*, the test of this latter works as for a control sequence entered but never defined.

1578.   ⟨ Cases for *conditional* 1450 ⟩ +≡
case *if_primitive_code*:
  { **do** *get_token*( ); **while** (¬(*cur_tok* ≠ *space_token*));
    if ((*cur_cs* ≠ 0) ∧ (*cur_cmd* ≠ *undefined_cs*) ∧ (*cur_cmd* < *call*)) *b* ← *true*;
    else *b* ← *false*;
  } **break**;

1579.   PROTE primitives changing definition or expansion.
The next primitives, here, are more involved since they are whether changing the definition of a control sequence, or modifying how the tokens will be treated.

1580.   Since a user level control sequence can give a new definition to a primitive, the `primitive`... primitive, if the argument is a control sequence whose name is the name of a primitive, will make this primitive meaning the meaning of the control sequence *hic et nunc*. If there was no primitive meaning, no error is raised and nothing is changed. It can be seen as a kind of `expand_after` command since it is in the external handling of the token list creation.

Since we need to redefine the token and hence give a valid control sequence in the *eqtb*, we have defined *frozen_primitive*. This "frozen" is, actually, not quite frozen by itself since we will redefine its values according to the primitive definition we have to restablish momentarily. But it is indeed "permanent" since it only refers to the permanently defined meanings. Hence, the initialization of the *frozen_primitive* address is just to document the code: these values will be overwritten on each actual call.

⟨ Generate all PROTE primitives 1555 ⟩ +≡
    primitive("`primitive`", *expand_after*, *primitive_code*); *text*(*frozen_primitive*) ← *text*(*cur_val*);
    eqtb[*frozen_primitive*] ← *eqtb*[*cur_val*];

1581.   ⟨ Cases of *expandafter* for *print_cmd_chr* 1447 ⟩ +≡
case *primitive_code*: *print_esc*("`primitive`"); **break**;

1582.   The problem is that the primitives are added at *level_one* and that a redefinition as a macro at this same level by a user simply overwrites the definition. We need then to keep these definitions.

Primitives are only added by INITEX. So we can consider what we will call a ROM, since it can be only "flashed" by INITEX and is read-only afterwards, a kind of BIOS table holding initial system calls (primitives).

Since primitives are not macros (they don't need to expand or to evaluate parameters since their definition is directly in the code), the definition of a primitive is a couple: the command class (*cur_cmd*) and the modifier (*cur_chr*) to distinguish between the cases—the instances. But since, at the user level, a primitive is identified by its name, and that a redefinition is, mandatorily, a homonym, the location of the macro shadowing the primitive is at the same address as was the primitive in the *eqtb*. So in order to speed-up the check, we should organize things so that the address in the *eqtb* of a control sequence (one character or multiletter) can be readily converted in an address in the ROM array.

This array will be an array of memory word, of type **two_halves**, in order to re-use the macro definitions set for the table of equivalents.

The one character primitives are added by direct addressing relative to *single_base*. The multiletter primitives are added starting at *frozen_control_sequence* $- 1$, downwards; but there are only, at the moment, 322 multileter primitives defined by TeX, 78 such primitives defined by ε-TeX, and we are adding 24 more. It is clear that, looking at primitives, region 2 of *eqtb* is really a sparse array and that, when *hash_size* is increased for format needs, there will be a fair amount of space wasted if we simply copy, in fact, second part of region 1 and region 2 in the ROM.

Yes, but it is simpler as a first approach—premature optimization is the root of all evil. So a simple translation scheme will be enough.

The index in ROM will start at 1 and will go up to $256 + 1 + hash\_size$, that is a simple translation from *single_base* to *ROM_base*, but only for addresses of interest, the other pointing to an *ROM_undefined_primitive* that will allow an easy test.

#**define** *ROM_base* 1
#**define** *ROM_size* $(256 + 1 + hash\_size)$ ▷ 256 oc, undefined and ml ◁
#**define** *ROM_undefined_primitive* 257
#**define** *ROM_type_field*(*A*) *A.hh.b0*
#**define** *ROM_equiv_field*(*X*) *X.hh.rh*
#**define** *ROM_type*(*A*) *ROM_type_field*(ROM[*A*])   ▷ command code for equivalent ◁
#**define** *set_ROM_p_from_cs*(*A*)
        if $((A \geq single\_base) \wedge (A < frozen\_control\_sequence))$ $p \leftarrow A - single\_base + ROM\_base$;
        else $p \leftarrow ROM\_undefined\_primitive$

⟨ Global variables 13 ⟩ +≡
    static memory_word ROM0[*ROM_size* $-$ *ROM_base* $+ 1$], ∗**const** ROM $\leftarrow$ ROM0 $-$ *ROM_base*;

1583.   Even if it will be unused in TeX or ε-TeX modes, we will initialize it since we add code to the *primitive* procedure and we need TeX and ε-TeX ones to be registered as well, whether INITEX switches to PR0TE mode later or not.

⟨ Initialize table entries (done by INITEX only) 164 ⟩ +≡
    ROM[*ROM_undefined_primitive*] $\leftarrow$ *eqtb*[*undefined_control_sequence*];
    for $(k \leftarrow ROM\_base$; $k \leq 256$; $k{+}{+})$ ROM[*k*] $\leftarrow$ ROM[*ROM_undefined_primitive*];
    for $(k \leftarrow ROM\_undefined\_primitive + 1$; $k \leq ROM\_size$; $k{+}{+})$ ROM[*k*] $\leftarrow$ ROM[*ROM_undefined_primitive*];

1584.   When a primitive is added—and this only happens in INITEX—we have to define the corresponding address in the ROM.

1585.   *cur_val* has the pointer in second part of region 1 or in region 2 of *eqtb*.

⟨ Add primitive definition to the ROM array 1585 ⟩ ≡
    set_ROM_p_from_cs(*cur_val*); ROM[*p*] $\leftarrow$ *eqtb*[*cur_val*];

This code is used in section 264.

1586. This array has to be dumped since it is only defined by INITEX. It is always dumped even if it is unused unless in PRoTE mode.

⟨Dump the ROM array 1586⟩ ≡
  for $(k \leftarrow ROM\_base; \; k \leq ROM\_size; \; k{+}{+})$ *dump_wd*(ROM$[k]$);

This code is used in section 1307.

1587. And what has been dumped shall be undumped.

⟨Undump the ROM array 1587⟩ ≡
  for $(k \leftarrow ROM\_base; \; k \leq ROM\_size; \; k{+}{+})$ *undump_wd*(ROM$[k]$);

This code is used in section 1308.

1588. Once all this is done, the processing of \primitive is simple: we read the next token that has to be a control sequence. If this control sequence belongs to region 1 or 2 and is defined in ROM, we redefine the token to be the *frozen_primitive* control sequence, redefining its codes from the ROM and setting the text associated for printing purposes. If not, the token is unchanged. Then we put back the token so that it will be processed again, maybe redefined.

⟨Cases for *expandafter* 1588⟩ ≡
case *primitive_code*:
  { *get_token*( ); *set_ROM_p_from_cs*(*cur_cs*);
    if $((p \neq ROM\_undefined\_primitive) \wedge (ROM\_type(p) \neq undefined\_cs))$ {
      eqtb[*frozen_primitive*] ← ROM$[p]$; *text*(*frozen_primitive*) ← *text*(*cur_cs*);
      cur_tok ← *cs_token_flag* + *frozen_primitive*;
    }
    back_input( );
  } **break**;

See also section 1592.

This code is used in section 367.

1589. The next primitive changes the expansion of its argument that is like a general text expanded, except that protected macros (an ε-TEX extension) are not extanded.

1590. ⟨Generate all PRoTE primitives 1555⟩ +≡
  primitive("expanded", *expand_after*, *expanded_code*);

1591. ⟨Cases of *expandafter* for *print_cmd_chr* 1447⟩ +≡
case *expanded_code*: *print_esc*("expanded");

1592. This intervenes in *expand* and we must substitute a token list to our current token, putting it back for further reprocessing.

⟨Cases for *expandafter* 1588⟩ +≡
case *expanded_code*:
  { *scan_general_x_text*( ); *back_list*(*link*(*link*(*garbage*))); *free_avail*(*link*(*garbage*));
      ▷ drop reference count ◁
  }

1593.   PROTE strings related primitives.

The primitive `\strcmp` text two parameters that are general text without expansion. The two token lists created are converted to strings and this couple of strings is then compared, character by character. If the first string is lexicographically sorted before the second, the expansion is -1; if the two strings are equal, the expansion is 0; if the first string is lexicographically sorted after the second, the expansion is 1.

⟨ Generate all PROTE primitives 1555 ⟩ +≡
  $primitive($`"strcmp"`$, convert, strcmp\_code);$

1594.   ⟨ Cases of *convert* for *print_cmd_chr* 1558 ⟩ +≡
case $strcmp\_code$: $print\_esc($`"strcmp"`$);$ **break**;

1595.   It should be noted that the strings comparison is TEX strings comparison: the arguments are subject to the manipulation done when scanning a general text (squeezing non escaped blanks), and the characters are converted according to the *xord* array. Thus it is an **ASCII_code**—in the TEX sense explained at the very beginning of the web file, part 2—comparison and the result is the same, as long as relative characters are mapped to the same value, whatever the system. Nul strings are valid.

⟨ Cases of 'Scan the argument for command *c*' 1559 ⟩ +≡
case $strcmp\_code$:
  { $scan\_general\_x\_text($ $);$ $toks\_to\_str($ $);$ $s \leftarrow info(garbage);$ $flush\_list(link(garbage));$
    $scan\_general\_x\_text($ $);$ $toks\_to\_str($ $);$ $t \leftarrow info(garbage);$ $flush\_list(link(garbage));$
    if $((length(s) \equiv 0) \wedge (length(t) \equiv 0))$ $cur\_val \leftarrow 0;$
    else if $(length(s) \equiv 0)$ $cur\_val \leftarrow -1;$
    else if $(length(t) \equiv 0)$ $cur\_val \leftarrow 1;$
    else { $m \leftarrow str\_start[s];$ $n \leftarrow str\_start[t];$ $r \leftarrow false;$
      while $((\neg r) \wedge (m < str\_start[s+1]) \wedge (n < str\_start[t+1]))$ { $cur\_val \leftarrow str\_pool[m] - str\_pool[n];$
        if $(cur\_val \neq 0)$ $r \leftarrow true;$
        $incr(m);$ $incr(n);$
      }

case $strcmp\_code$: $print\_int(cur\_val);$ **break**;

1597.   PRᴏᴛE date and time related primitives.
    The following primitives are related to the time elapsed since a defined moment in time. The creation date is fixed at the moment when *fix_date_and_time* has been called and stays fixed afterwards. This moment is also, by default, the reference moment for computing the time elapsed.

1598.   The creation date is retrieved by the \creationdate primitive. As explained above, the date corresponds to the moment when *fix_date_and_time* was called taking into account FORCE_SOURCE_DATE and SOURCE_DATE_EPOCH (see above, m.241). If the creation date is forced, the string will be UTC related.
    The format of the string is *D*: *YYYYMMDDHHmmSSOHH* "mm", 'O' being the relationship of local time to UT, that is '-' (minus), '+' or 'Z'; HH followed by a single quote being the absolute value of the offset from UT in hours (00–23), mm followed by a single quote being the absolute value of the offset from UT in minutes (00–59). All fields after the year are optional and default to zero values.

1599.   ⟨ Generate all PRᴏᴛE primitives 1555 ⟩ +≡
  primitive("creationdate", *convert*, *creation_date_code*);

1600.   ⟨ Cases of *convert* for *print_cmd_chr* 1558 ⟩ +≡
case *creation_date_code*: *print_esc*("creationdate"); **break**;

1601.   *get_creation_date* has to be provided by the system.
⟨ Cases of 'Scan the argument for command *c*' 1559 ⟩ +≡
case *creation_date_code*: *get_creation_date*( ); **break**;

1602.   The date is in the *time_str* so we have simply to convert the characters.
⟨ Cases of 'Print the result of command *c*' 1560 ⟩ +≡
case *creation_date_code*:
  for (*k* ← 0; *time_str*[*k*] ≠ '\0'; *k*++) *print_char*(*time_str*[*k*]); **break**;

1603.   The time elapsed is a scaled integer the unit being scaled seconds, i.e. 1/65536 of a second. Since our scaled integers have a defined range, the value can not reach or pass, in plain seconds, 32767.
    The elapsed time returned is relative to some defined moment. At start, the reference moment is the time the date was set for *fix_date_and_time*. This requires system support and the default implementation here will then fix this moment at noon on 4 July 1776 and what would be returned by the function is here simply defined by a macro: with this reference time and this basic code, *infinity* is the permanent answer.
  #**define** *get_elapsed_time*   *infinity*   ▷ a function should be implemented ◁

1604.   ⟨ Generate all PRᴏᴛE primitives 1555 ⟩ +≡
  primitive("resettimer", *extension*, *reset_timer_code*);
  primitive("elapsedtime", *last_item*, *elapsed_time_code*);

case *elapsed_time_code*: *print_esc*("elapsedtime"); **break**;

1606.   ⟨ Cases of *extension* for *print_cmd_chr* 1606 ⟩ ≡
case *reset_timer_code*: *print_esc*("resettimer"); **break**;
See also section 1681.
This code is used in section 1346.

1607.   ⟨ Cases for fetching a PRᴏᴛE int value 1557 ⟩ +≡
case *elapsed_time_code*: *cur_val* ← *get_elapsed_time*; **break**;

1608. The reference moment can be reset by a call to the primitive `\resettimer`. It simply resets the reference moment to the moment the primitive was called. The counter is not regularily incremented. When asked about the time elapsed what is returned is the difference, in scaled seconds, from the moment of the call to the moment of reference. So there is no persistent variable neither a kind of clock implemented.

Standard Pascal doesn't provide related routines so our syntactically correct but semantically useless routines are implemented here: the *reset_timer* does nothing, while the *get_elapsed_time* simply returns, even when *reset_timer* has been called, the invalid value *infinity*.

#**define** *reset_timer*   *do_nothing*

1609. Since to reset the timer a simple call to the routine is necessary, we simply add it to `main_control` by adding it to the cases handled by `do_extension`. It contributes nothing to the token list: it is a "fire and forget", so no need to handle the special `subtype` in the other hooks.

⟨ Cases for *do_extension* 1609 ⟩ ≡
case *reset_timer_code*: *reset_timer*; **break**;

See also section 1682.

This code is used in section 1348.

1610.   PROTE file related primitives.
The presence of the following primitives in the engine can be questioned. Since they are very external, and their implementation, for example in C, requires things that are not in the C standard (the date of modification of the file, for example). So these should not be multiplied.

1611.   The `\filesize` primitive expands to the size, in bytes, of the file.
⟨ Generate all PROTE primitives 1555 ⟩ +≡
  primitive("filesize", *convert*, *file_size_code*);

1612.   ⟨ Cases of *convert* for *print_cmd_chr* 1558 ⟩ +≡
case *file_size_code*: *print_esc*("filesize"); **break**;

1613.   In order to be able to treat the problem when trying to open the file, we open here and pass the file pointer, if success, to a dedicated function in order to get its size. In case of problem, nothing is returned.
⟨ Cases of 'Scan the argument for command *c*' 1559 ⟩ +≡
case *file_size_code*:
  { *scan_general_x_text*( ); *toks_to_str*( ); *s* ← *info*(*garbage*); *flush_list*(*link*(*garbage*)); *str_to_name*(*s*);
    cur_val ← −1;   ▷ invalid value if error ◁
    cur_val ← *get_file_size*( ); *flush_string*;
  } **break**;

1614.   ⟨ Cases of 'Print the result of command *c*' 1560 ⟩ +≡
case *file_size_code*:
  if (*cur_val* ≠ −1) *print_int*(*cur_val*); **break**;

1615.   The `\filemoddate` expands to a date with the same format as the creation date (see `\creationdate`).
⟨ Generate all PROTE primitives 1555 ⟩ +≡
  primitive("filemoddate", *convert*, *file_mod_date_code*);

1616.   ⟨ Cases of *convert* for *print_cmd_chr* 1558 ⟩ +≡
case *file_mod_date_code*: *print_esc*("filemoddate"); **break**;

1617.   For getting the argument, the treatment resembles that of `\filesize` obviously, since it is only the type of information returned that changes. The availability of this information in system dependent. The information shall be set in *xchg_buffer*.
In this basic implementation, we set the string to the empty one by simply setting *xchg_buffer_length* to 0.
#**define** *get_file_mtime*   *xchg_buffer_length* ← 0
⟨ Cases of 'Scan the argument for command *c*' 1559 ⟩ +≡
case *file_mod_date_code*:
  { *scan_general_x_text*( ); *toks_to_str*( ); *s* ← *info*(*garbage*); *flush_list*(*link*(*garbage*)); *str_to_name*(*s*);
    get_file_mod_date( ); *flush_string*;
  } **break**;

1618.   Printing the result consists simply in printing every **text_char** in *time_str*. If the length is 0, nothing is printed.
⟨ Cases of 'Print the result of command *c*' 1560 ⟩ +≡
case *file_mod_date_code*:
  for (*k* ← 0; *time_str*[*k*] ≠ '\0'; *k*++) *print_char*(*time_str*[*k*]); **break**;

1619. The primitive `\filedump` expands to the dump of the first `length` bytes of the file, starting from `offset`. Offset and length are optional integers given, in that order, introduced resp. by the keywords "offset" and "length". If not specified, they default to 0. A length of 0 expands to nothing (it is not an error). The file name is given as a *general text*.

⟨ Generate all PROTE primitives 1555 ⟩ +≡
  primitive("filedump", *convert*, *file_dump_code*);

1620. ⟨ Cases of *convert* for *print_cmd_chr* 1558 ⟩ +≡
case *file_dump_code*: *print_esc*("filedump"); **break**;

1621. The scanning of the arguments is obvious from the syntax above.

Since "offset" and "length" may be given in that order, we assign the variables `k` and `l`, in alphabetical order. These have to be positive or nul values.

Contrary to other blocks, and for optimization purposes (in order not to clobber the string pool with data that we can read, when necessary, one byte at a time), `k`, `l` and `f` will be defined here and used when printing.

⟨ Cases of 'Scan the argument for command *c*' 1559 ⟩ +≡
case *file_dump_code*:
  { *k* ← 0; *l* ← 0;   ▷ defaults ◁
    if (*scan_keyword*("offset")) { *scan_int*( );
      if (*cur_val* < 0) { *print_err*("Bad␣"); *print_esc*("filedump");
        help2("I␣allow␣only␣nonnegative␣values␣here.",
        "I␣changed␣this␣one␣to␣zero."); *int_error*(*cur_val*);
      }
      else *k* ← *cur_val*;
    }
    if (*scan_keyword*("length")) { *scan_int*( );
      if (*cur_val* < 0) { *print_err*("Bad␣"); *print_esc*("filedump");
        help2("I␣allow␣only␣nonnegative␣values␣here.",
        "I␣changed␣this␣one␣to␣zero."); *int_error*(*cur_val*);
      }
      else *l* ← *cur_val*;
    }
    scan_general_x_text( ); *toks_to_str*( ); *s* ← *info*(*garbage*); *flush_list*(*link*(*garbage*)); *str_to_name*(*s*);
    flush_string;   ▷ this one was the filename argument ◁
  } **break**;

1622.   The variables have been set, and the file name has been defined. We simply print the uppercase hexadecimal transcription of every byte requested before closing the file. Here we deal with bytes (`eight_bits` values) so there is no transcription.

⟨ Cases of 'Print the result of command c' 1560 ⟩ +≡

case *file_dump_code*:
```
  {
     FILE *f ← fopen((char *) name_of_file0, "rb");
     if (f ≠ Λ) { fseek(f, k, SEEK_SET);
        do {
           i ← fgetc(f);
           if (i ≡ EOF) break;
           dig[0] ← i % 16;  dig[1] ← i/16;  print_the_digs(2);  decr(l);
        } while (¬(feof(f) ∨ (l ≡ 0)));
        fclose(f);
     }
  } break;
```

1623.   The `\mdfivesum` is obviously a variant of the `convert` class since it takes values from external and put them as a token list in the stream.

⟨ Generate all PROTE primitives 1555 ⟩ +≡

   primitive("mdfivesum", *convert*, *mdfive_sum_code*);

1624.   ⟨ Cases of *convert* for *print_cmd_chr* 1558 ⟩ +≡

case *mdfive_sum_code*: *print_esc*("mdfivesum"); **break**;

1625.   There is an optional keyword "file" that will tell us if the $<$ *general text* $>$ is to be taken as a filename or just as the string to hash. The $<$ *balanced text* $>$ is expanded in both cases.

   Once this is done, we ask to init the MD5 state; then fill the exchange buffer with chunks of data and update the MD5 hash with every chunk until source is exhausted and ask for the final (16 bytes numerical value) result that will be put in the *xchg_buffer*.

   Since we are looking for a "general text", that must be enclosed (at least: ended; the opening brace can be implicit) by a *right_brace*, an error will be caught with runaways.

   The general text is converted to a string. It is legal to have an empty string if the argument is not a file.

⟨ Cases of 'Scan the argument for command c' 1559 ⟩ +≡

case *mdfive_sum_code*:
```
  { r ← scan_keyword("file");  scan_general_x_text();  toks_to_str();  s ← info(garbage);
     flush_list(link(garbage));  l ← get_md5_sum(s, r);  flush_string;
        ▷ done with the filename or string to hash ◁
  } break;
```

1626.   As a result, there is 16 bytes in the *md5_digest* representing the MD5 hash. We simply print, byte by byte, the uppercase hexadecimal representation of this hash.

⟨ Cases of 'Print the result of command c' 1560 ⟩ +≡

case *mdfive_sum_code*:
```
  for (k ← 0;  k < l;  k++) { dig[0] ← md5_digest[k] % 16;  dig[1] ← md5_digest[k]/16;  print_the_digs(2);
  } break;
```

1627.   This is something that we will be doing several times. We have scanned a general text. The result is a token list that we will interpret as a file name. We must then put this name in *name_of_file* and try to open it, as a binary file.

cur_area and *cur_ext* are not set: we use the string as is.

⟨ Generate the MD5 hash for a file 1627 ⟩ ≡
    { *str_to_name*(*s*); *xchg_buffer_length* ← 0;   ▷ empty if file not opened ◁
      if ((*name_length* ≤ *file_name_size*) ∧ (*b_open_in*(&*data_in*))) { *mdfive_init*; *r* ← *false*;
            ▷ reset it to indicate eof ◁
        while (¬*r*) { **if** (*xchg_buffer_length* ≡ 64) *mdfive_update*;   ▷ resets length ◁
          if (¬*eof*(*data_in*)) { *pascal_read*(*data_in*, *i*); *xchg_buffer*[*xchg_buffer_length* + 1] ← *i*;
            incr(*xchg_buffer_length*);
          }
          else *r* ← *true*;
        }
        if (*xchg_buffer_length* ≠ 0) *mdfive_update*;   ▷ treats remaining ◁
        b_close(&*data_in*); *mdfive_final*;   ▷ may yield the empty file/nul string hash if nothing input ◁
      }
    }

1628.   For a string, the procedure is very similar. It is not an error for the string to be the null one.

⟨ Generate the MD5 hash for a string 1628 ⟩ ≡
    { *mdfive_init*; *xchg_buffer_length* ← 0;   ▷ proceed by 64 chunks ◁
      for (*k* ← *str_start*[*s*]; *k* ≤ *str_start*[*s* + 1] − 1; *k*++) { **if** (*xchg_buffer_length* ≡ 64) *mdfive_update*;
            ▷ resets length ◁
        xchg_buffer[*xchg_buffer_length* + 1] ← *xchr*[*so*(*str_pool*[*k*])]; *incr*(*xchg_buffer_length*);
      }
      if (*xchg_buffer_length* ≠ 0) *mdfive_update*;   ▷ treats remaining ◁
      mdfive_final;
    }

1629.   A MD5 hash signature can be requested for a stream of bytes, this being a string directly passed or a file.

Since the MD5 algorithm does a lot of bitwise operations, a standard Pascal implementation has not been attempted. But since we aim to limitate and to segregate the calls to external routines so that they do not tamper with the internals of TeX, we have to find a way to communicate with the routines.

1630.   To obtain the MD5 hash signature of a file will need an external implementation, since the algorithm requires bitwise operation that standard Pascal does not provide. So we do not bother to try. The present implementation returns nothing.

1631.   *mdfive_init* shall reinit the state to compute the hash value. Nothing is taken from *xchg_buffer* and *xchg_buffer_length* is unchanged.

#**define** *mdfive_init*   *do_nothing*

1632.   *mdfive_update* takes *xchg_buffer_length* bytes to contribute to the hash. The bytes being consumed, *xchg_buffer_length* shall be reset to 0.

#**define** *mdfive_update*   *xchg_buffer_length* ← 0

1633.   *md5_final* puts the binary 16 bytes long hash into *xchg_buffer* and sets *xchg_buffer_length* to 16.

Here, by default, we do nothing except carefully set *xchg_buffer_length* to 0 in order to state that we have consumed the data.

#**define** *mdfive_final*   *xchg_buffer_length* ← 0

1634.   Pseudo-random number generation.

These routines come from John Hobby's METAPOST and generate pseudo-random numbers with the additive scheme recommended in Section 3.6 of *The Art of Computer Programming*; however, the results are random fractions between 0 and $mpfract\_one - 1$, inclusive.

METAPOST uses 28 significant bits of precision and we have kept this in order for the routines to behave the same way as in METAPOST. So the name *mpfract* will be used instead of **scaled**, while the two are integers, in the range defined by TEX.

#**define double**(A) $A \leftarrow A + A$ ▷ multiply a variable by two ◁
#**define** $halfp(A)$ $(A)/2$ ▷ when quantity is known to be positive or zero ◁

1635.   The subroutines for logarithm and exponential involve two tables. The first is simple: $two\_to\_the[k]$ equals 2^k. The second involves a bit more calculation, which the author claims to have done correctly: $spec\_log[k]$ is 2^{27} times $\ln\big(1/(1 - 2^{-k})\big) = 2^{-k} + \frac{1}{2}2^{-2k} + \frac{1}{3}2^{-3k} + \cdots$, rounded to the nearest integer.

⟨ Global variables 13 ⟩ +≡

   for $(k \leftarrow 14;\ k \leq 27;\ k\mathrm{++})\ spec\_log[k] \leftarrow two\_to\_the[27 - k]$;
   $spec\_log[28] \leftarrow 1$;

1637.   Here is the routine that calculates 2^8 times the natural logarithm of a **scaled** quantity; it is an integer approximation to $2^{24}\ln(x/2^{16})$, when x is a given positive integer.

The method is based on exercise 1.2.2–25 in *The Art of Computer Programming*: During the main iteration we have $1 L 2^{-30}x < 1/(1 - 2^{1-k})$, and the logarithm of $2^{30}x$ remains to be added to an accumulator register called y. Three auxiliary bits of accuracy are retained in y during the calculation, and sixteen auxiliary bits to extend y are kept in z during the initial argument reduction. (We add $100 \cdot 2^{16} = 6553600$ to z and subtract 100 from y so that z will not become negative; also, the actual amount subtracted from y is 96, not 100, because we want to add 4 for rounding before the final division by 8.)

#**define** $\mathit{mpfract\_four}$ ° 10000000000 ▷ 2^{30}, represents 4.00000000 ◁

⟨ Types in the outer block 18 ⟩ +≡
  typedef int mpfract;   ▷ this type is used for pseudo-random numbers ◁

1641.   The *make_mpfract* routine produces the **mpfract** equivalent of $p/(\textbf{double})\,q$, given integers p and q; it computes the integer $f = \lfloor 2^{28}p/q + \frac{1}{2} \rfloor$, when p and q are positive. If p and q are both of the same scaled type t, the "type relation" *make_mpfract*$(t, t) \equiv$ **mpfract** is valid; and it's also possible to use the subroutine "backwards," using the relation *make_mpfract*$(t, \textbf{mpfract}) \equiv t$ between scaled types.

If the result would have magnitude 2^{31} or more, *make_mpfract* sets *arith_error* $\leftarrow$ *true*. Most of TeX's internal computations have been designed to avoid this sort of error.

If this subroutine were programmed in assembly language on a typical machine, we could simply compute $(2^{28}*p)/q$, since a double-precision product can often be input to a fixed-point division instruction. But when we are restricted to Pascal arithmetic it is necessary either to resort to multiple-precision maneuvering or to use a simple but slow iteration. The multiple-precision technique would be about three times faster than the code adopted here, but it would be comparatively long and tricky, involving about sixteen additional multiplications and divisions.

The present implementation is highly portable, but slow; it avoids multiplication and division except in the initial stage. But since it is not part of TeX inner loop, it doesn't matter.

      negate(q); negative ← ¬negative;
   }
   n ← p/q;  p ← p % q;
   if (n ≥ 8) { arith_error ← true;
      if (negative) return −el_gordo; else return el_gordo;
   }
   else {  n ← (n − 1) * mpfract_one;  ⟨ Compute f = ⌊2²⁸(1 + p/q) + ½⌋ 1642 ⟩;
      if (negative) return −(f + n); else return f + n;
   }
 }
```

1642.   The **do** { loop here preserves the following invariant relations between f, p, and q: (i) $0 \leq p < q$; (ii) $fq + p = 2^k(q + p_0)$, where k is an integer and p_0 is the original value of p.

Notice that the computation specifies $(p-q)+p$ instead of $(p+p)-q$, because the latter could overflow. Let us hope that optimizing compilers do not miss this point; a special variable *be_careful* is used to emphasize the necessary order of computation. Optimizing compilers should keep *be_careful* in a register, not store it in memory.

$\langle$ Compute $f = \lfloor 2^{28}(1 + p/q) + \frac{1}{2} \rfloor$ $1642\rangle \equiv$
  $f \leftarrow 1;$
  do {
    be_careful $\leftarrow p - q;$ $p \leftarrow$ *be_careful* $+ p;$
    if $(p \geq 0)$ $f \leftarrow f + f + 1;$
    else { **double**$(f);$ $p \leftarrow p + q;$
    }
  } **while** $(\neg(f \geq mpfract\_one));$
  be_careful $\leftarrow p - q;$ **if** $(be\_careful + p \geq 0)$ $incr(f)$

This code is used in section 1641.

1643.   The dual of *make_mpfract* is *take_mpfract*, which multiplies a given integer q by a fraction f. When the operands are positive, it computes $p = \lfloor qf/2^{28} + \frac{1}{2} \rfloor$, a symmetric function of q and f.

$\langle$ Declare PROTE arithmetic routines $1637\rangle$ $+\equiv$
  static int *take_mpfract*(**int** q, **mpfract** f)
  { **int** $p;$ ▷ the fraction so far ◁
    bool *negative*;   ▷ should the result be negated? ◁
    int $n;$ ▷ additional multiple of q ◁
    int *be_careful*;   ▷ disables certain compiler optimizations ◁

    $\langle$ Reduce to the case that $f \geq 0$ and $q > 0$ $1644\rangle;$
    if $(f < mpfract\_one)$ $n \leftarrow 0;$
    else { $n \leftarrow f/mpfract\_one;$ $f \leftarrow f$ % $mpfract\_one;$

      randoms[*k*] ← *x*;
    }
    for (*k* ← 24; *k* ≤ 54; *k*++) { *x* ← *randoms*[*k*] − *randoms*[*k* − 24];
      if (*x* < 0) *x* ← *x* + *mpfract_one*;
      randoms[*k*] ← *x*;
    }
    j_random ← 54;
  }

1657.   To initialize the *randoms* table, we call the following routine.

⟨ Declare PROTE arithmetic routines 1637 ⟩ +≡
  static void *init_randoms*(**void**)
  { **mpfract** *j*, *jj*, *k*;   ▷ more or less random integers ◁
    int *i*;   ▷ index into *randoms* ◁
    j ← *abs*(*random_seed*);
    while (*j* ≥ *mpfract_one*) *j* ← *halfp*(*j*);
    k ← 1;
    for (*i* ← 0; *i* ≤ 54; *i*++) { *jj* ← *k*; *k* ← *j* − *k*; *j* ← *jj*;
      if (*k* < 0) *k* ← *k* + *mpfract_one*;
      randoms[(*i* ∗ 21) % 55] ← *j*;
    }
    new_randoms( ); *new_randoms*( ); *new_randoms*( );   ▷ "warm up" the array ◁
  }

1658.   To produce a uniform random number in the range $0 \leq u < x$ or $0 \geq u > x$ or $0 \equiv u \equiv x$, given a **scaled** value x, we proceed as shown here.

Note that the call of *mult_integers* will produce the values 0 and x with about half the probability that it will produce any other particular values between 0 and x, because it rounds its answers.

⟨ Declare PROTE arithmetic routines 1637 ⟩ +≡
```
  static scaled unif_rand (scaled x)
  { scaled y;      ▷ trial value ◁

    next_random; y ← take_mpfract (abs (x), randoms [j_random]);
    if (y ≡ abs (x)) return 0;
    else if (x > 0) return y;
    else return −y;
  }
```

1659.   This can be used by calling the following primitive.

⟨ Generate all PROTE primitives 1555 ⟩ +≡
```
  primitive ("uniformdeviate", convert, uniform_deviate_code);
```

1660.   ⟨ Cases of *convert* for *print_cmd_chr* 1558 ⟩ +≡
```
case uniform_deviate_code: print_esc ("uniformdeviate"); break;
```

1661.   It takes one integer argument obviously that will be the argument to the function.

⟨ Cases of 'Scan the argument for command c' 1559 ⟩ +≡
```
case uniform_deviate_code:
  { scan_int (); cur_val ← unif_rand (cur_val);

1669.   ⟨Cases of 'Print the result of command c' 1560⟩ +≡
case $normal\_deviate\_code$: $print\_int(cur\_val)$;

1670.   DVI related primitives.
These primitives are related to positions in the DVI output.

The TEX and DVI system coordinates relate to an origin that is at the upper left corner. The TEX coordinates are computed relative to an origin that has $(0,0)$ coordinates. Coordinates grow then rightward and downward. This is the *page* coordinates relative to what is typeset (what TEX is dealing with).

But this typesetting material has to be put on what we will call *paper*. The material put into shape by TEX is put on the paper. On this paper, where will be put the TEX origin? It is considered to be $1in$ at the right and $1in$ down from the upper left corner of the paper (see m.590, alinea 2).

#**define** $DVI\_std\_x\_offset$ 4736286   ▷ 1 inch in sp ◁
#**define** $DVI\_std\_y\_offset$ 4736286   ▷ 1 inch in sp ◁

1671.   But the paper size is not specified in the DVI file and is not being dealt with by TEX.

In order to have a common reference point, and since the \lastxpos and \lastypos primitives originated in pdfTEX, these two primitives give positions, in scaled points, relative to the lower left corner of the paper.

Hence the need, for these primitive, to define the paper size, with the (misnamed) \pagewidth and \pageheight.

\pagewidth and \pageheight are dimension parameters, initialized to 0 by the generic TEX code.

⟨ Generate all PROTE primitives 1555 ⟩ +≡
  $primitive($"pagewidth"$, assign\_dimen, dimen\_base + page\_width\_code);$
  $primitive($"pageheight"$, assign\_dimen, dimen\_base + page\_height\_code);$

1672.   When instructed to, the h and v last values are transformed, in the coordinates system defined above and saved in the global variables $last\_saved\_xpos$ and $last\_saved\_ypos$. They are initialized to 0 and we do not make any verification that a call to the \savepos primitive—to come—has been made before retrieving their values.

⟨ Global variables 13 ⟩ +≡
  static scaled $last\_saved\_xpos, last\_saved\_ypos;$ ▷ last (x,y) DVI pos saved ◁

1673.   ⟨ PROTE initializations 1569 ⟩ +≡
  $last\_saved\_xpos \leftarrow 0; \ last\_saved\_ypos \leftarrow 0;$

1674.   ⟨ Set $last\_saved\_xpos$ and $last\_saved\_ypos$ with transformed coordinates 1674 ⟩ ≡
  $last\_saved\_xpos \leftarrow cur\_h + DVI\_std\_x\_offset;$
  $last\_saved\_ypos \leftarrow page\_height - (cur\_v + DVI\_std\_y\_offset);$
This code is used in section 1687.

1675.   ⟨ Generate all PROTE primitives 1555 ⟩ +≡
  $primitive($"lastxpos"$, last\_item, last\_xpos\_code);$
  $primitive($"lastypos"$, last\_item, last\_ypos\_code);$

1676.   ⟨ Cases of $last\_item$ for $print\_cmd\_chr$ 1382 ⟩ +≡
case $last\_xpos\_code$: $print\_esc($"lastxpos"$);$ **break**;
case $last\_ypos\_code$: $print\_esc($"lastypos"$);$ **break**;

1677.   ⟨ Cases for fetching a PROTE int value 1557 ⟩ +≡
case $last\_xpos\_code$: $cur\_val \leftarrow last\_saved\_xpos;$ **break**;
case $last\_ypos\_code$: $cur\_val \leftarrow last\_saved\_ypos;$

1678. *last_saved_xpos* and *last_saved_ypos* are only defined when instructed to by the call the the the \savepos primitive. Since the real work has to be done at shipout time, it is a case to be treated like the \special primitive, that is it belongs to the extension class.

We will add something more in the handling of the primitive: it will insert a whatsit in the DVI file so that one, using the program *dvitype*, could retrieve more than one *hic*. So there is a counter incremented whenever the primitive is called.

⟨ Global variables 13 ⟩ +≡
    static int *last_save_pos_number*;   ▷ identifying the order of the call ◁

1679. ⟨ PRoTE initializations 1569 ⟩ +≡

    image_name(*p*) ← *n*; *image_area*(*p*) ← *a*; *image_ext*(*p*) ← *e*; *fn* ← *hfile_name*(*n*, *a*, *e*);
    i ← *hnew_file_section*(*fn*); *image_no*(*p*) ← *i*;
    image_xwidth(*p*) ← *image_xheight*(*p*) ← *image_alt*(*p*) ← *null*; *image_aspect*(*p*) ← 0; **return** *p*;
  }

1698.   Creating parameter nodes.   The *new_param_node* function adds parameter nodes to the current list. It should be possible to check the parameter values against those stored in the definition section and remove the ones that are unchanged. It would make the parameter lists shorter, saving some time when setting and restoring them later. There is probably not much savings in memory space, because most of the time a reference number is found for the parameter list.

⟨ HiTEX routines 1696 ⟩ +≡
  static void *new_param_node*(**uint8_t** *t*, **uint8_t** *n*, **int** *v*)
  { **pointer** *p*;
    ⟨ Create the parameter node 1699 ⟩
    ⟨ Initialize the parameter node 1700 ⟩
    link(*p*) ← *link*(*temp_head*); *link*(*temp_head*) ← *p*;
  }

1699.   ⟨ Create the parameter node 1699 ⟩ ≡
  p ← *get_node*(*param_node_size*); *type*(*p*) ← *whatsit_node*; *subtype*(*p*) ← *param_node*;

  else {
    free_node(*p*, *param_node_size*); QUIT("Undefined␣parameter␣type␣%d", *t*);
  }
This code is used in section 1698.

1701. Hyphenation. While the breaking of a paragraph into lines must be postponed because `hsize` is not known, hyphenation should be done as part of HiTeX because we want to keep hyphenation out of the viewer. Therefore HiTeX will do hyphenation for all words within a paragraph.

There is a fine point to observe here: TeX will consider a word as a candidate for automatic hyphenation only if the world "follows" after a glue. (For the exact rules, see Appendix H of the TeX-book.) As a consequence, TeX usually does not submit the first word of a paragraph to its hyphenation routine. Viewing paragraphs that start with a lengthy word on a narrow display therefore often look more unsightly than necessary: the long word sticks out into the right margin as much as it can. To remedy this situation, HiTeX has a "`[-no]-hyphenate-first-word`" option. If set, which is the default, HiTeX will deviate from TeX's rules and submit the first word of a paragraph to the hyphenation algorithm.

The next problem arises from TeX's multipass approach to line breaking and the attempt to have HiTeX choose exactly the same line breaks as TeX does: TeX distinguishes between discretionary breaks inserted by the author of a text, and discretionary breaks discovered by the hyphenation routine. The latter, called here "automatic", are used only in pass two and three of the line breaking routine.

The function *hline_break* follows:

$\langle$ HiTeX routines 1696 $\rangle +\equiv$
  static void *hline_break*(**int** *final_widow_penalty*)

1702.   Currently HiTEX dos not implement the parshape feature of TEX. The implementation of `\list`
in LATEX does, however, depend on a simple use of parshape where all lines have the same length and
indentation. We cover this special case be using a hanging indentation and adjusting the paragraph width
by the difference of the normal `\hsize` and the given length.

⟨ fix simple use of parshape 1702 ⟩ ≡
  {
    $last\_special\_line \leftarrow info(par\_shape\_ptr) - 1;$
    if $(last\_special\_line \neq 0)$
      $\text{DBG}(\text{DBGTEX}, \text{"Warning}_\sqcup\text{parshape}_\sqcup\text{with}_\sqcup\text{n=\%d}_\sqcup\text{not}_\sqcup\text{yet}_\sqcup\text{implemented"}, info(par\_shape\_ptr));$
    $second\_width \leftarrow mem[par\_shape\_ptr + 2 * (last\_special\_line + 1)].sc;$
    $second\_indent \leftarrow mem[par\_shape\_ptr + 2 * last\_special\_line + 1].sc;$
    $par\_extent(pp) \leftarrow new\_xdimen(second\_indent + second\_width, par\_shape\_hfactor, par\_shape\_vfactor);$
    $second\_width \leftarrow second\_width + round((\textbf{double})\, par\_shape\_hfactor * hhsize/unity +$
        $(\textbf{double})\, par\_shape\_vfactor * hvsize/unity);\ par\_shape\_fix \leftarrow true;$
  }
This code is used in section 1701.

1703. Links, Labels, and Outlines.   The HINT format knows about labels, links, and outlines. When generating a short format HINT file, links are part of the content section, where as labels and outlines are found in the definition section. Because labels are defined while writing the content section, the writing of labels and outlines must be postponed. For that reason, we store information about labels and outlines in dynamic arrays, and map labels, which are identified by a name or a number, to their index using a dynamic hash table.

We start with two functions that allocate new entries in the dynamic arrays increasing their size if necessary.

⟨ HiT$_E$X auxiliary routines 1703 ⟩ ≡
```
  static int next_label(void)
  {
    static int label_no ← −1;
    static int labels_allocated ← 0;

    label_no ++;
    if (label_no > #FFFF) overflow("labels", #FFFF);
    if (label_no ≥ labels_allocated) {
      if (labels_allocated ≡ 0) {
        labels_allocated ← 32; ALLOCATE(labels, labels_allocated, Label);
      }
      else RESIZE(labels, labels_allocated, Label);
    }
    max_ref[label_kind] ← label_no; return label_no;
  }
  static int next_outline(void)
  {
    static int outlines_allocated ← 0;
    static int outline_no ← −1;

    outline_no ++;
    if (outline_no > #FFFF) overflow("outlines", #FFFF);
    if (outline_no ≥ outlines_allocated) {
      if (outlines_allocated ≡ 0) {
        outlines_allocated ← 32; ALLOCATE(outlines, outlines_allocated, Outline);
      }
      else RESIZE(outlines, outlines_allocated, Outline);
    }
    max_outline ← outline_no; return outline_no;
  }
```
See also sections 1704, 1705, 1706, 1707, 1708, 1709, 1710, 1715, 1720, 1737, 1746, 1747, 1748, 1749, 1755, 1761, 1765, 1771, 1772, 1774, 1777, 1778, 1782, 1792, 1793, 1794, 1796, 1807, 1809, 1814, 1816, 1832, and 1833.

This code is used in section 1694.

1704. While processing the content nodes, access to the labels is provided either by name or by number through a hash table. We store table entries in linked lists starting with a reasonably sized table of pointers. This keeps the fixed costs low and guards against overflow and rapidly increasing inefficiency. We start with a function to insert a new entry into the hash table.

⟨ HiTEX auxiliary routines 1703 ⟩ +≡
```
typedef struct hash_entry {
  int num;
  char *nom;
  uint16_t n;
  struct hash_entry *next;
} HashEntry;
#define LABEL_HASH 1009     ▷ MIX a prime number ◁
static HashEntry *label_hash[LABEL_HASH] ← {Λ};

static int insert_hash(int h, int num, char *nom)
{
  HashEntry *e;
  ALLOCATE(e, 1, HashEntry);  e→n ← next_label();
  if (nom ≠ Λ) e→nom ← strdup(nom);
  else e→num ← num;
  e→next ← label_hash[h];  label_hash[h] ← e;
  if (e→nom ≠ Λ) DBG(DBGLABEL, "Creating␣new␣label␣*%d:␣name='%s'\n", e→n, e→nom);
  else DBG(DBGLABEL, "Creating␣new␣label␣*%d:␣num=%d\n", e→n, e→num);
  return e→n;
}
```

1705. There are two cases: finding a label by name or by number. We start with the simpler case where the number is given. The process is straight forward:

⟨ HiTEX auxiliary routines 1703 ⟩ +≡
```
static int find_label_by_number(int p)
{
  unsigned int h ← (unsigned int) p % LABEL_HASH;
  HashEntry *e ← label_hash[h];
  while (e ≠ Λ)
    if (e→nom ≡ Λ ∧ e→num ≡ p) return e→n;
    else e ← e→next;
  return insert_hash(h, p, Λ);
}
```

1706.   To look up a label by its name as given by a token list, we prepare ourselves by implementing two functions: one to extract the character codes from the token list forming the "name" and one to compute the hash value for a name. The routine to find the label by name is then equivalent to the routine we have just seen. Given a pointer p to either a label, a link, or an outline node, the function *find_label* returns the correct label reference. Currently, we limit label names to at most 255 significant byte.

$\langle$ HiTEX auxiliary routines 1703 $\rangle$ $+\equiv$
```
  static char *tokens_to_name(pointer p)
  {
    static char s[256];
    int i ← 0;
    bool skip_space ← 0;
    while (i < 255 ∧ p ≠ 0)
    {
      int m ← info(p)/°400; int c ← info(p) % °400;
      if (m ≡ spacer ∧ ¬skip_space)
      {
        s[i++] ← '␣'; skip_space ← true; }
      else if ((m ≡ letter ∨ m ≡ other_char) ∧ '␣' < c ∧ c < #7F)
      { s[i++] ← c; skip_space ← false; }
      p ← link(p);
    }
    s[i] ← 0; return s;
  }
  static unsigned int name_hash(char *s)
  {
    unsigned int h ← 0;
    while (*s ≠ 0) h ← (h ≪ 2) + *(s++);
    return h;
  }
  static int find_label_by_name(pointer p)
  {
    char *s ← tokens_to_name(link(p));
    unsigned int h ← name_hash(s) % LABEL_HASH;
    HashEntry *e ← label_hash[h];
    while (e ≠ Λ)
      if (e→nom ≠ Λ ∧ strcmp(e→nom, s) ≡ 0) return e→n;
      else e ← e→next;
    return insert_hash(h, 0, s);
  }
```

1707.   We combine both ways of finding a label reference in the following function:

$\langle$ HiTEX auxiliary routines 1703 $\rangle$ $+\equiv$
```
  static int find_label(pointer p)
  { if (label_has_name(p)) return find_label_by_name(label_ptr(p));
    else return find_label_by_number(label_ptr(p));
  }
```

1708. After these preparations, we can implement the functions needed when labels, links, and outlines are delivered to the page builder.

We start with looking at the labels: When a labels is defined, the current position is recorded. Further labels are linked together in order of descending positions, to allow the efficient adjustment of label positions when moving lists.

⟨ HiTeX auxiliary routines 1703 ⟩ +≡
```
  static void new_label(pointer p)
  {
    int n ← find_label(p);
    if (n ≠ zero_label_no ∧ labels[n].where ≠ LABEL_UNDEF) {
      MESSAGE("WARNING:␣Ignoring␣duplicate␣definition␣of␣label␣");
      if (label_has_name(p)) MESSAGE("name␣%s\n", tokens_to_name(link(label_ptr(p))));
      else MESSAGE("num␣%d\n", label_ptr(p));
    }
    else {
      labels[n].where ← label_where(p);  labels[n].pos ← hpos − hstart;  labels[n].pos0 ← hpos0 − hstart;
      labels[n].next ← first_label;  first_label ← n;
      DBG(DBGLABEL, "Defining␣label␣*%d:␣pos=0x%x\n", n, labels[n].pos);
    }
  }
```

1709. When a link node is written to the output, we can check that start links and end links properly match.

⟨ HiTeX auxiliary routines 1703 ⟩ +≡
```
  static int last_link ← −1;
  static int new_start_link(pointer p)
  {
    int n ← find_label(p);
    if (last_link ≥ 0) fatal_error("Missing␣end␣link␣before␣start␣link");
    labels[n].used ← true;  last_link ← n;  DBG(DBGLABEL, "New␣link␣to␣label␣*%d\n", n);  return n;
  }
  static int new_end_link(void)
  {
    int n;
    if (last_link < 0) fatal_error("Missing␣start␣link␣before␣end␣link");
    n ← last_link;  last_link ← −1;  return n;
  }
```

1710. For outline nodes, we use the next two functions. The node list representing the title can be an arbitrary list in horizontal mode. In general, the front end should be able to render such a horizontal list, but at least it should be able to extract the UTF8 character codes and display those.

⟨ HiT$_E$X auxiliary routines 1703 ⟩ +≡
  static void *new_outline*(**pointer** *p*)
  {
     int *r* ← *find_label*(*p*);
     int *m* ← *next_outline*( );
     List *l*;
     uint32_t *pos*;

     pos ← *hpos* − *hstart*; *l.t* ← TAG(*list_kind*, *b001*);   ▷ this eventually should be a text ◁
     hout_list_node(*outline_ptr*(*p*), *pos*, &*l*); *hset_outline*(*m*, *r*, *outline_depth*(*p*), *pos*);
     DBG(DBGLABEL, "New␣outline␣for␣label␣*%d\n", *r*);
  }

1711. One last function is needed which is called when the *outline_group* ends that was started after scanning the \HINToutline primitive.

⟨ HiT$_E$X routines 1696 ⟩ +≡
  static void *hfinish_outline_group*(**void**)
  {
     pointer *s* ← *link*(*head*);
     unsave( ); *pop_nest*( ); *outline_ptr*(*tail*) ← *s*;
  }

1712.   The New Page Builder.   Here is the new *build_page* routine of HiTEX:

⟨ HiTEX routines 1696 ⟩ +≡
  static void *build_page*(**void**)
  {
    static bool *initial* ← *true*;
    if (*link*(*contrib_head*) ≡ *null* ∨ *output_active*) **return**;
    do {
      pointer *p* ← *link*(*contrib_head*);
      pointer *q* ← *null*;   ▷ for output nodes ◁
      pointer *∗t* ← Λ;   ▷ the tail of the output nodes ◁
      bool *eject* ← (*type*(*p*) ≡ *penalty_node* ∧ *penalty*(*p*) ≤ *eject_penalty*);
      int *page_penalty* ← 0;
      if (*eject*) *page_penalty* ← *penalty*(*p*);
      ⟨ Record the bottom mark 1725 ⟩
      ⟨ Suppress empty pages if requested 1714 ⟩
      link(*contrib_head*) ← *link*(*p*); *link*(*p*) ← *null*;
      if (*link*(*contrib_head*) ≡ *null*) {
        ⟨ Make the contribution list empty by setting its tail to *contrib_head* 995 ⟩;
      }
      update_last_values(*p*); ⟨ Freeze the page specs if called for 1713 ⟩
      page_goal ← #3fffffff;   ▷ maximum dimension ◁
      t ← *collect_output*(&*p*, &*q*);
      if (*p* ≠ *null*) {
        hpos0 ← *hpos*; *hout_node*(*p*);
      }
    recycle_p: *flush_node_list*(*p*);
      if (*q* ≠ *null* ∨ (*eject* ∧ *page_contents* ≥ *box_there*)) {
        geq_word_define(*int_base* + *output_penalty_code*, *page_penalty*);
      empty_output: ⟨ Fire up the output routine for *q* 1722 ⟩
      }
    } **while** (*link*(*contrib_head*) ≠ *null*);
    DBG(DBGBUFFER, "after␣build␣page␣dyn_used=␣%d\n", *dyn_used*);
  }

1713.   When the *page_contents* changes from *empty* to not *empty*, the function *hint_open* will open the output file. While the output file is needed only much later in the function *hput_hint*, this place was chosen to match, as close as possible, the behavior of the original TEX.

⟨ Freeze the page specs if called for 1713 ⟩ ≡
  if (*page_contents* < *box_there*) {
    switch (*type*(*p*)) {
    case *whatsit_node*:

          vpack_node ∧ *subtype*(*p*) ≠ *par_node* ∧ *subtype*(*p*) ≠ *disp_node* ∧ *subtype*(*p*) ≠
          image_node ∧ *subtype*(*p*) ≠ *align_node*) **break**;   ▷ else fall through ◁
    case *hlist_node*: **case** *vlist_node*: **case** *rule_node*:
      if (*page_contents* ≡ *empty*) {
        hint_open( ); *freeze_page_specs*(*box_there*); *hfix_defaults*( );
      }
      else *page_contents* ← *box_there*;
      break;
    case *ins_node*:
      if (*page_contents* ≡ *empty*) {
        hint_open( ); *freeze_page_specs*(*inserts_only*); *hfix_defaults*( );
      }
      break;
    case *kern_node*: **case** *penalty_node*: **case** *glue_node*: **goto** *recycle_p*;
    default: **break**;
    }
  }

This code is used in section 1712.

1714.   Users of TEX often force the generation of empty pages for example to start a new chapter on a right hand page with an odd page number. This makes sense for a printed book but not for a screen reader where there are no page numbers nor right or left hand pages. Using a screen reader, empty pages are just annoying. The common way to achieve an empty page is the use of `\eject` followed by a an empty box, a fill glue, and another `\eject`.

The following code tries to detect such a sequence of nodes and will eliminate them if requested. To do so, we delay the output of nodes after an eject penalty until either something gets printed on the page or another eject penalty comes along. To override the delayed output, a penalty less or equal to a double *eject_penalty* can be used. The function *its_all_over* is an example for such a use. It seems that the eliminated nodes do not contain anything of value for the output routine, but the output routine might have other resources, like the first column of a two column page, which it might put back on the contribution list. So it is wise to call the output routine and give it a chance.

⟨ Suppress empty pages if requested 1714 ⟩ ≡
 if $(option\_no\_empty\_page \wedge ((eject \wedge penalty(p) > 2 * (eject\_penalty)) \vee (page\_contents \equiv$
   $empty \wedge \neg is\_visible(p))))$ {
  pointer $r, prev\_r \leftarrow p$;
  loop {
   $r \leftarrow link(prev\_r)$;
   if $(r \equiv null)$ **return**;
   else if $(is\_visible(r))$ **break**;
   else if $(type(r) \equiv penalty\_node \wedge penalty(r) \leq eject\_penalty)$ {
    $q \leftarrow p$; $link(prev\_r) \leftarrow null$; $link(contrib\_head) \leftarrow r$;
    DBG(DBGPAGE, "Eliminating␣empty␣page␣preceding␣penalty␣%d\n", $penalty(r)$);
    $geq\_word\_define(int\_base + output\_penalty\_code, penalty(r))$; **goto** $empty\_output$;
   }
   $prev\_r \leftarrow r$;
  }
 }

This code is used in section 1712.

1715.   It remains to test a node for visibility. This is a quick (and dirty) test because the test will not look inside boxes; it simply tests whether the list pointer is *null*. We consider an *open_node*, *write_node*, *close_node*, *label_node*, or *outline_node* as visible because deleting them could cause unwanted side effects. Possibly it would be better to regard them as invisible, but still pass them on to the rest of the output routine.

⟨ HiTeX auxiliary routines 1703 ⟩ +≡
  static bool *is_visible*(**pointer** *p*)
  {
    switch (*type*(*p*)) {
    case *penalty_node*: **case** *kern_node*: **case** *glue_node*: **case** *mark_node*: **return** *false*;

      else if (*subtype*(*p*) ≡ *par_node*) **return** *par_list*(*p*) ≠ *null*;
      else return *false*;
    default: **return** *true*;
    }
  }

1716.   Because we will need this procedure in the *its_all_over* function. We add a forward declaration

⟨ Forward declarations 52 ⟩ +≡
  static bool *is_visible*(**pointer** *p*);

1717.   An important feature of the new routine is the call to *hfix_defaults*. It occurs when the first "visible mark" is placed in the output. At that point we record the current values of TEX's parameters which we will use to generate the definition section of the HINT file. It is still possible to specify alternative values for these parameters by using parameter lists but only at an additional cost in space and time.

Furthermore, this is the point where we freeze the definition of *hsize* and *vsize*. The current values will be regarded as the sizes as recommended by the author.

From then on *hsize* and *vsize* are replaced by the equivalent extended dimensions and any attempt to modify them on the global level will be ignored. *hhsize* and *hvsize* will contain the sizes that a regular TEX engine would use.

We also compute the total page size from the page template defined last.

⟨ Compute the page size 1717 ⟩ ≡
```
  {
    pointer p;
    p ← link(setpage_head);
    if (p ≡ null) {
      scaled margin;
      if (hhsize < hvsize) margin ← hhsize;
      else margin ← hvsize;
      margin ← margin/6 − 6 ∗ unity;
      if (margin < 0) margin ← 0;
      page_h ← hhsize + 2 ∗ margin;  page_v ← hvsize + 2 ∗ margin;
    }
    else {
      pointer x;
      x ← setpage_height(p);  page_v ← xdimen_width(x) + round(((double) xdimen_hfactor(x) ∗ hhsize +
          (double) xdimen_vfactor(x) ∗ hvsize)/unity);
      x ← setpage_width(p);  page_h ← xdimen_width(x) + round(((double) xdimen_hfactor(x) ∗ hhsize +
          (double) xdimen_vfactor(x) ∗ hvsize)/unity);
    }
  }
```
This code is used in section 1748.

1718.   ⟨ HiTEX variables 1718 ⟩ ≡
  static scaled *page_h*, *page_v*;

See also sections 1729, 1745, 1752, 1753, 1758, 1759, 1763, 1768, 1769, 1775, 1781, 1786, 1790, and 1808.
This code is used in section 1694.

1719.   ⟨ Switch *hsize* and *vsize* to extended dimensions 1719 ⟩ ≡
  hsize ← 0; *vsize* ← 0; *dimen_par_hfactor*(*hsize_code*) ← *unity*;
  dimen_par_vfactor(*vsize_code*) ← *unity*;
This code is used in section 1749.

1720.   There is one point where we can not simply forgo the output routine: `\write` commands. Unless the `\write` is decorated with an `\immediate`, the whatsit node generated from it will lay dormant in the contribution list (and later the page) until the output routine passes it as part of the finished page to the *ship_out* routine. There it will come to life and write its token list out. The whatsit nodes from `\openout` and `\closeout` commands behave similarly.

It is not possible to ignore the output routine because the output routine may change the environment in which the token list of a `\write` will be expanded. For example LATEX redefines `\protect` to be `\noexpand`. As a consequence we have to implement a simplified version of TEX's usual process to fire up the output routine.

The *collect_output* routine takes a node list $*p$, removes the output nodes and appends them to $*q$, with q always pointing to the tail pointer.

⟨ HiTEX auxiliary routines 1703 ⟩ +≡
```
static pointer *collect_output(pointer *p, pointer *q)
{
    while (*p ≠ null) {
        ⟨ Collect output nodes from *p 1721 ⟩
        p ← &(link(*p));
    }
    return q;
}
```

1721. TeX does not permit output nodes in leaders, so we don't check them; further we do not check the pre- and post-break lists of discretionary breaks.

⟨ Collect output nodes from $*p$ 1721 ⟩ ≡
  if ($\neg is\_char\_node(*p)$) {
    pointer $r \leftarrow *p$;
    switch ($type(r)$) {

1727.   Now we consider the various whatsit nodes that are new in HiTEX. In most cases, it is no longer possible to determine the dimensions so that the *hpack* function is forced to return a hpack node. The hpack nodes cause special trouble when converting mlists to hlists because there the dimensions are necessary for positioning the parts of the formulas. A clean solution requires to postpone such computations to the HINT viewer. For now we adopt a simpler solution and supply an educated guess which is reasonable since the boxes that occur in math formulas are often not very complicated. *graph_node*s should not be in a horizontal list, and *disp_node*s should be only inside *graph_node*s.

1729. Streams. HINT stream numbers start at 0 for the main text and continue upwards. TEX, on the other hand, numbers insertions starting with `box255` for the main text and continues downwards. Some mapping is needed, and we use the array *insert2stream* to map TEX's insert numbers to HINT stream numbers. The predefined stream for the main content has stream number 0.

⟨HiTEX variables 1718⟩ +≡
  static int *insert2stream*[#100] ← {0};

1730. The following function returns the stream number for a given insert number i with $255 > i \geq 0$. A new stream number is allocated if necessary. Note that no overflow test is necessary since TEX allocates less than 233 inserts. The initial value of *max_ref*[*stream_kind*] is 0 and therefore stream number 0, reserved for the main content, is never allocated. Stream definitions might also be loaded as part of a format file. Then the maximum stream number is stored in *max_stream*. So if we do not find a stream number in the *insert2stream* array, we scan the stream definitions once and cache the associations found there.

⟨HiTEX routines 1696⟩ +≡
  static int *hget_stream_no*(**int** i)
  {
    static bool *init* ← *false*;
    int s;
    if $(i \equiv 0)$ **return** 0;
    $s \leftarrow insert2stream[i]$;
    if $(s \neq 0)$ **return** s;

      $max\_ref[stream\_kind] \leftarrow max\_stream;\ init \leftarrow true$;
    }
    $s \leftarrow insert2stream[i]$;
    if $(s \equiv 0)\ s \leftarrow insert2stream[i] \leftarrow max\_ref[stream\_kind] \leftarrow {+}{+}max\_stream$;
    return s;
  }

1731. Stream Definitions.

A stream definition is stored as a whatsit node with subtype *setstream_node*. Given a pointer p to such a node, here are the macros used to access the data stored there:

- *setstream_number*(p) the HINT stream number n.
- *setstream_insertion*(p) the corresponding TEX insertion number i.
- *setstream_max*(p) the maximum height x: This extended dimension is the maximum size per page for this insertion.
- *setstream_mag*(p) the magnification factor f: Inserting a box of height h will contribute $h * f/1000$ to the main page.
- *setstream_preferred*(p) the preferred stream p: If $p \geq 0$ we move the insert to stream p if possible.
- *setstream_next*(p) the next stream n: If $n \geq 0$ we move the insert to stream n if it can not be accommodated otherwise.
- *setstream_ratio*(p) the split ratio r: If $r > 0$ split the final contribution of this stream between stream p and n in the ratio $r/1000$ for p and $1 - r/1000$ for n before contributing streams p and n to the page.
- *setstream_before*(p) the "before" list b: For a nonempty stream the material that is added before the stream content.
- *setstream_after*(p) the "after" list a: For a nonempty stream the material that is added after the stream content.
- *setstream_topskip*(p) the top skip glue t: This glue is inserted between the b list and the stream content and adjusted for the height for the first box of the stream content.
- *setstream_width*(p) the width w: This extended dimension is the width used for example to break paragraphs in the stream content into lines.
- *setstream_height*(p) a glue specification h reflecting the total height, stretchability and shrinkability of the material in lists a and b.

Currently HiTEX handles only normal streams. First or last streams will come later.

The stream definition nodes are created and initialized with the following function:

⟨ HiTEX routines 1696 ⟩ +≡

```
static pointer new_setstream_node(uint8_t n)
{
    pointer p ← get_node(setstream_node_size);

    type(p) ← whatsit_node; subtype(p) ← setstream_node; setstream_insertion(p) ← n;
    setstream_number(p) ← hget_stream_no(n); setstream_mag(p) ← 1000;
    setstream_preferred(p) ← 255; setstream_next(p) ← 255; setstream_ratio(p) ← 0;
    setstream_max(p) ← new_xdimen(0, 0, ONE); setstream_width(p) ← new_xdimen(0, ONE, 0);
    setstream_topskip(p) ← zero_glue; add_glue_ref(zero_glue); setstream_height(p) ← zero_glue;
    add_glue_ref(zero_glue); setstream_before(p) ← null; setstream_after(p) ← null; return p;
}
```

1732.   The preferred stream, the next stream, and the split ratio are scanned as part of the \setstream
primitive. When TEX finds the right brace that terminates the stream definition, it calls *handle_right_brace*.
Then it is time to obtain the remaining parts of the stream definition. For insertion class i, we can extract
the maximum height x of the insertions from the corresponding dimen$i$ register the magnification factor f
from the count$i$ register, and the total height h from the skip$i$ register. The width w is taken from \hsize
and the topskip t from \topskip.

⟨HiTEX routines 1696⟩ +≡
  static void *hfinish_stream_group*(**void**)
  {
    pointer s;
    end_graf( ); $s \leftarrow hget\_current\_stream$( );
    if $(s \neq null)$ {
      pointer t;
      uint8_t i;
      $i \leftarrow setstream\_insertion(s)$; $setstream\_mag(s) \leftarrow count(i)$;
      $setstream\_width(s) \leftarrow new\_xdimen(dimen\_par(hsize\_code), dimen\_par\_hfactor(hsize\_code),$
          $dimen\_par\_vfactor(hsize\_code))$; $t \leftarrow zero\_glue$; $add\_glue\_ref(t)$;
      $delete\_glue\_ref(setstream\_topskip(s))$; $setstream\_topskip(s) \leftarrow t$; $t \leftarrow skip(i)$; $add\_glue\_ref(t)$;
      $delete\_glue\_ref(setstream\_height(s))$; $setstream\_height(s) \leftarrow t$;
      $setstream\_max(s) \leftarrow new\_xdimen(dimen(i), dimen\_hfactor(i), dimen\_vfactor(i))$;
    }
    unsave( ); *flush_node_list*(*link*(*head*)); *pop_nest*( );
  }

1733.   The before list b and the after list a are defined using the \HINTbefore and \HINTafter primitives.
When the corresponding list has ended with a right brace, TEX calls *handle_right_brace* and we can store
the lists.

⟨HiTEX routines 1696⟩ +≡
  static void *hfinish_stream_before_group*(**void**)
  {
    pointer s;
    end_graf( ); $s \leftarrow hget\_current\_stream$( );
    if $(s \neq null)$ $setstream\_before(s) \leftarrow link(head)$;
    unsave( ); *pop_nest*( );
  }
  static void *hfinish_stream_after_group*(**void**)
  {
    pointer s;
    end_graf( ); $s \leftarrow hget\_current\_stream$( );
    if $(s \neq null)$ $setstream\_after(s) \leftarrow link(head)$;
    unsave( ); *pop_nest*( );
  }

1734.   Page Template Definitions.

The data describing a page template is stored in a whatsit node with subtype *setpage_node*. Given a pointer p to such a node, here are the macros used to access the data stored there:

• *setpage_name*(p): The name of the page template can be used in the user interface of a HINT viewer.

• *setpage_number*(p): The number of the page template that is used in the HINT file to reference this page template.

• *setpage_id*(p): The number of the page template that is used in TeX to reference this page template.

• *setpage_priority*(p): The priority helps in selecting a page template.

• *setpage_topskip*(p): The topskip glue is added at the top of a page and adjusted by the height of the first box on the page.

• *setpage_height*(p): The height of the full page including the margins.

• *setpage_width*(p): The width of the full page including the margins.

• *setpage_depth*(p): The maximum depth of the page content. If the last box is deeper than this maximum, the difference is subtracted from the height of the page body.

• *setpage_list*(p): The list that defines the page template. After the page builder has completed a page this list is scanned and page body and nonempty streams are added at the corresponding insertion points.

• *setpage_streams*(p): The list of stream definitions that belong to this page template.

To allow TeX to use arbitrary numbers between 1 and 255 for the page templates while in HINT the numbers of page templates are best consecutive from 1 to $max\_ref[page\_kind] \equiv max\_page$, we let TeX assign an id and generate the template number. Because templates might be in format files, the variable max_page will hold the true number.

The function *new_setpage_node* is called with the page template id $0 < i < 256$ and a string number for the name n. It allocates and initializes a node if necessary and moves it to the front of the list of templates.

⟨HiTeX routines 1696⟩ +≡

```
static pointer new_setpage_node(uint8_t i, str_number n)
{
    pointer p, prev_p;

    prev_p ← setpage_head;
    for (p ← link(prev_p); p ≠ null; prev_p ← p, p ← link(p))
        if (setpage_id(p) ≡ i) break;
    if (p ≡ null) ⟨Allocate a new setpage_node p 1735⟩
    else link(prev_p) ← link(p);
    link(p) ← link(setpage_head); link(setpage_head) ← p; return p;
}
```

1735.   ⟨Allocate a new *setpage_node* p 1735⟩ ≡

```
{
    p ← get_node(setpage_node_size); type(p) ← whatsit_node; subtype(p) ← setpage_node;
    setpage_number(p) ← max_ref[page_kind] ← ++max_page; setpage_id(p) ← i; setpage_name(p) ← n;
    setpage_priority(p) ← 1; setpage_topskip(p) ← zero_glue; add_glue_ref(zero_glue);
    setpage_height(p) ← new_xdimen(0, 0, ONE); setpage_width(p) ← new_xdimen(0, ONE, 0);
    setpage_depth(p) ← max_depth; setpage_list(p) ← null; setpage_streams(p) ← null;
}
```

This code is used in section 1734.

1736.   The default values are replaced by parameters given to the \setpage primitive and by the current values of certain TEX registers when finishing the page template.

⟨ HiTEX routines 1696 ⟩ +≡

  static void *hfinish_page_group*(**void**)
  {
    uint8_t *k*;
    pointer *p*, *q*, *r*;
    end_graf( ); *p* ← *hget_current_page*( );

    return *s*;
  }

1738.   HINT Output.   Here are the routines to initialize and terminate the output. The initialization is done in three steps: First we allocate the data structures to write nodes into buffers; this requires a directory and buffers for sections 0, 1, and 2.

1739.   ⟨HiTEX routines 1696⟩ +≡
  static void *hout_allocate*(**void**)
  {
    new_directory(*dir_entries*); *new_output_buffers*( ); *max_section_no* ← 2; *hdef_init*( );
    hput_content_start( ); ⟨insert an initial language node 1811⟩
  }

1740.   Second we initialize the definitions and start the content section before the first content node is written; this is done when the *page_contents* is about to change from *empty* to not *empty*. Finally, the actual output file *hout* needs to be opened; this must be done before calling *hput_hint* which is already part of the termination routines. It is placed, however, much earlier because asking for the output file name—according to TEX's conventions—should come before the first item is put on the first page by the page builder.

⟨HiTEX routines 1696⟩ +≡
  static void *hint_open*(**void**)
  {
    if (*job_name* ≡ 0) *open_log_file*( );
    pack_job_name(".hnt");
    while (¬(*hout* ← *open_out*((**char** ∗) *name_of_file* + 1, "wb")))
      prompt_file_name("file␣name␣for␣output", ".hnt");
    output_file_name ← *make_name_string*( );
    DBG(DBGBASIC, "Output␣file␣%s␣opened\n", (**char** ∗) *name_of_file* + 1);
  }
#**define** HITEX_VERSION "1.1"
  static void *hput_definitions*( );
  extern int *option_global*;
  static void *hout_terminate*(**void**)
  {
    size_t *s*;
    if (*hout* ≡ Λ) **return**;
    hput_content_end( ); *hput_definitions*( ); *option_global* ← *true*;   ▷ use global names in the directory ◁
    hput_directory( ); *s* ← *hput_hint*("created␣by␣HiTeX␣Version␣"HITEX_VERSION);
    ⟨record the names of files in optional sections 1741⟩
    print_nl("Output␣written␣on␣"); *slow_print*(*output_file_name*); *print*("␣(1␣page,␣"); *print_int*(*s*);
    print("␣bytes).");
  }
  static void *hint_close*(**void**)
  {
    hout_terminate( );
    if (*hout* ≠ Λ) *fclose*(*hout*);
    hout ← Λ;
  }

1741. The file name recording feature of HiTEX makes it necessary to record the names of the files that are added as optional sections. This feature is not part of the *hput_optional_sections* function which is called from *hput_hint*. The following simple loop will achieve this.

⟨ record the names of files in optional sections 1741 ⟩ ≡
```
{
    int i;
    for (i ← 3; i ≤ max_section_no; i++) recorder_record_input(dir[i].file_name);
}
```
This code is used in section 1740.

1742.   The HINT Directory.   There is not much to do here: some code to find a new or existing directory entry, a variable to hold the number of directory entries allocated, a function to allocate a new file section, and an auxiliary function to convert TeX's file names to ordinary C strings.

⟨ Find an existing directory entry 1742 ⟩ ≡
>   **for** $(i \leftarrow 3; \ i \leq max\_section\_no; \ i{+}{+})$
>   **if** $(dir[i].file\_name \neq \Lambda \wedge strcmp(dir[i].file\_name, file\_name) \equiv 0)$ **return** i;

This code is used in section 1746.

1743.   ⟨ Allocate a new directory entry 1743 ⟩ ≡
> $i \leftarrow max\_section\_no; \ i{+}{+};$
>   **if** $(i > {}^{\#}\text{FFFF})$ QUIT("Too␣many␣file␣sections");
>   **if** $(i \geq dir\_entries)$ RESIZE(dir, $dir\_entries$, $Entry$);
> $max\_section\_no \leftarrow i;$
>   **if** $(max\_section\_no > {}^{\#}\text{FFFF})$ QUIT("Too␣many␣sections");
> $dir[i].section\_no \leftarrow i;$

This code is used in section 1746.

1744.   ⟨ HiTeX macros 1744 ⟩ ≡
#define RESIZE(P, S, T)
>   {
>   **int** $\_n \leftarrow (S) * 1.4142136 + 0.5;$
>   **if** $(\_n < 32) \ \_n \leftarrow 32;$
>   {
>   REALLOCATE($P, \_n, T$); $memset((P) + (S), 0, (\_n - (S)) * sizeof(T)); \ (S) \leftarrow \_n;$
>   }
>   }

See also sections 1756 and 1797.

This code is used in section 1694.

1745.   ⟨ HiTeX variables 1718 ⟩ +≡
>   **static int** $dir\_entries \leftarrow 4;$

1746.   ⟨ HiTeX auxiliary routines 1703 ⟩ +≡
>   **static uint16_t** $hnew\_file\_section(\textbf{char } *file\_name)$
>   {
>   **uint16_t** $i;$
>
>   ⟨ Find an existing directory entry 1742 ⟩
>   ⟨ Allocate a new directory entry 1743 ⟩
> $dir[i].file\_name \leftarrow strdup(file\_name);$ **return** $i;$
>   }

1747.   The following function uses TEX's function *pack_file_name* to create a new filename from a name n, a directory or "area" a, and an extension e. TEX will truncate the new filename to *file_name_size* characters without warning. The new function will take a *name_length* equal to *file_name_size* as an indication that truncation has taken place and terminates the program. The return value converts a Pascal array, starting with index 1, into a C array starting with index 0.

⟨ HiTEX auxiliary routines 1703 ⟩ +≡
    static char ∗*hfile_name*(**str_number** n, **str_number** a, **str_number** e)
    {
      pack_file_name(n, a, e, Λ);
      if (*name_length* ≥ *file_name_size*)
        QUIT("File␣name␣too␣long␣%d␣>=␣%d", *name_length*, *file_name_size*);
      return (**char** ∗) *name_of_file* + 1;
    }

1748. HINT Definitions.   Definitions are used for two reasons: they provide default values for the parameters that drive TEX's algorithms running in the HINT viewer, and they provide a compact notation for HINT content nodes.

To find the optimal coding for a HINT file, a global knowledge of the HINT file is necessary. This would require a two pass process: in the first pass HiTEX could gather statistics on the use of parameter values and content nodes as a basis for making definitions and in the second pass it could encode the content using these definitions. I consider it, however, more reasonable to write such a two pass optimizer as a separate program which can be used on any HINT file. Hence HiTEX uses a much simpler one pass approach:

HiTEX generates definitions for TEX-parameters using the values they have when the first non discardable item appears in *build_page*. This is usually the case after initial style files have been processed and we can expect that they set useful default values.

The procedure that generates these definitions is called *hfix_defaults*:

⟨ HiTEX auxiliary routines 1703 ⟩ +≡
  static void *hfix_defaults*(**void**)
  { **int** *i*;
    DBG(DBGDEF, "Freezing␣HINT␣file␣defaults\n"); ⟨ Compute the page size 1717 ⟩
    ⟨ Fix definitions for integer parameters 1754 ⟩
    ⟨ Fix definitions for dimension parameters 1760 ⟩
    ⟨ Fix definitions for glue parameters 1770 ⟩
    ⟨ Fix definitions of page templates 1799 ⟩
  }

1749.   Further, HiTEX generates definitions to be used in content nodes on the fly: Whenever a routine outputs an item for which a definition might be available, it calls a *hget_..._no* function. This function returns, if possible, the reference number of a suitable definition. If no definition is available, the function will try to allocate a new one, only if all reference numbers from 0 to #FF are already in use, a −1 is returned to indicate failure.

There are two possible problems with this approach: We might miss a very common item because it occurs for the first time late in the input when all reference numbers are already in use. For example an extensive index might repeat a certain pattern for each entry. And second, we might make a definition for an item that occurs only once. Taken together the definition plus the reference to it requires more space than the same item without a definition.

We can hope that the first effect does not occur too often, especially if the TEX file is short, and we know that the second effect is limited by the total number of definitions we can make plus four byte of overhead per instance.

Here we initialize the necessary data structures for definitions.

⟨ HiTEX auxiliary routines 1703 ⟩ +≡
  static void *hdef_init*(**void**)
  { **int** *i*;
    ⟨ Switch *hsize* and *vsize* to extended dimensions 1719 ⟩
    ⟨ Initialize definitions for extended dimensions 1764 ⟩
    ⟨ Initialize definitions for baseline skips 1776 ⟩
    ⟨ Initialize definitions for fonts 1791 ⟩
    ⟨ Initialize definitions for labels 1798 ⟩
#if 0
    overfull_rule ← 0;   ▷ no overfull rules please ◁
#endif
  }

1750.   After all definitions are ready, we write them using the function *hput_definitions*. When we output the definitions, we have to make sure to define references before we use them. This is achieved by using a specific ordering of the definitions in the function *hput_definitions* and by preventing the allocation of new definitions as soon as the output of the definition section has started. The latter has the additional benefit that the maximum values do no longer change.

⟨HiTeX routines 1696⟩ +≡
  static void *hput_definitions*( )   ▷ write the definitions into the definitions buffer ◁
  {
    int *i*;
    uint32_t *d, m, s*;

    hput_definitions_start( ); *hput_max_definitions*( ); ⟨Output language definitions 1812⟩
    ⟨Output font definitions 1795⟩
    ⟨Output integer definitions 1757⟩
    ⟨Output dimension definitions 1762⟩
    ⟨Output extended dimension definitions 1767⟩
    ⟨Output glue definitions 1773⟩
    ⟨Output baseline skip definitions 1779⟩
    ⟨Output parameter list definitions 1789⟩
    ⟨Output discretionary break definitions 1785⟩
    ⟨Output page template definitions 1801⟩
    hput_definitions_end( ); *hput_range_defs*( );   ▷ expects the definitions section to be ended ◁
    hput_label_defs( );
  }

1751.   In the following, we present for each node type the code to generate the definitions, using a common schema: We define a data structure called . . . _*defined*, to hold the definitions; we define, if applicable, the TeX-parameters; we add an *hget_*. . . _*no* function to allocate new definitions; and we finish with the code to output the collected definitions.

    Lets start with the most simple case: integers.

1752.   Integers.   The data structure to hold the integer definitions is a simple array with $^{\#}100$ entries. A more complex data structure, for example a hash table, could speed up searching for existing definitions but lets keep things simple for now.

⟨ HiTeX variables 1718 ⟩ +≡
  static int32_t *int_defined*[$^{\#}100$] ← {0};

1753.   Before we can generate definitions for TEX-parameters, we have to map TEX's parameter numbers to HINT definition numbers. While it seems more convenient here to have the reverse mapping, we need the mapping only once to record parameter definitions, but we will need it repeatedly in the function *hdef_param_node* and the overhead here does not warrant having the mapping in both directions.

⟨ HiTEX variables 1718 ⟩ +≡

```
static const int hmap_int[] ← {
    pretolerance_no,       ▷ pretolerance_code 0 ◁
    tolerance_no,          ▷ tolerance_code 1 ◁
    line_penalty_no,       ▷ line_penalty_code 2 ◁
    hyphen_penalty_no,     ▷ hyphen_penalty_code 3 ◁
    ex_hyphen_penalty_no,  ▷ ex_hyphen_penalty_code 4 ◁

    year_no,      ▷ year_code 23 ◁
    −1,     ▷ show_box_breadth_code 24 ◁
    −1,     ▷ show_box_depth_code 25 ◁
    −1,     ▷ hbadness_code 26 ◁
    −1,     ▷ vbadness_code 27 ◁
    −1,     ▷ pausing_code 28 ◁
    −1,     ▷ tracing_online_code 29 ◁
    −1,     ▷ tracing_macros_code 30 ◁
    −1,     ▷ tracing_stats_code 31 ◁
    −1,     ▷ tracing_paragraphs_code 32 ◁
    −1,     ▷ tracing_pages_code 33 ◁
    −1,     ▷ tracing_output_code 34 ◁
    −1,     ▷ tracing_lost_chars_code 35 ◁
    −1,     ▷ tracing_commands_code 36 ◁
    −1,     ▷ tracing_restores_code 37 ◁
    −1,     ▷ uc_hyph_code 38 ◁
    −1,     ▷ output_penalty_code 39 ◁
    −1,     ▷ max_dead_cycles_code 40 ◁
    hang_after_no,     ▷ hang_after_code 41 ◁
    floating_penalty_no    ▷ floating_penalty_code 42 ◁
};
```

1754.   Now we can generate the definitions for integer parameters:

⟨ Fix definitions for integer parameters 1754 ⟩ ≡
  $int\_defined[zero\_int\_no] \leftarrow 0;$
  for $(i \leftarrow pretolerance\_code;\ i \leq floating\_penalty\_code;\ i{+}{+})$
    if $(hmap\_int[i] \geq 0)$ $int\_defined[hmap\_int[i]] \leftarrow int\_par(i);$
  $max\_ref[int\_kind] \leftarrow \mathtt{MAX\_INT\_DEFAULT};$
This code is used in section 1748.

1755.   The function *hget_int_no* tries to allocate a predefined integer number; if not successful, it returns −1.

⟨ HiTEX auxiliary routines 1703 ⟩ +≡
  static int $hget\_int\_no(\textbf{int32\_t}\ n)$
  {
    int $i;$
    int $m \leftarrow max\_ref[int\_kind];$
    for $(i \leftarrow 0;\ i \leq m;\ i{+}{+})$
      if $(n \equiv int\_defined[i])$ **return** $i;$
    if $(m < {}^{\#}\mathtt{FF} \wedge section\_no \equiv 2)$ {
      $m \leftarrow {+}{+}max\_ref[int\_kind];$ $int\_defined[m] \leftarrow n;$ **return** $m;$
    }
    else return $-1;$
  }

1756.   Before we give the code to output an integer definition, we declare a macro that is useful for all the definitions. `HPUTDEF` takes a function F and a reference number R. It is assumed that F writes a definition into the output and returns a tag. The macro will then add the reference number and both tags to the output.

⟨ HiTEX macros 1744 ⟩ +≡
#**define** $\mathtt{HPUTDEF}(F, R)$
  {
    uint32_t $\_p;$
    uint8_t $\_f;$
    $\mathtt{HPUTNODE};$ ▷ allocate ◁
    $\_p \leftarrow hpos - hstart;$ $\mathtt{HPUT8}(0);$ ▷ tag ◁
    $\mathtt{HPUT8}(R);$ ▷ reference ◁
    $\_f \leftarrow F;$ $hstart[\_p] \leftarrow \_f;$ $\mathtt{DBGTAG}(\_f, hstart + \_p);$ $\mathtt{DBGTAG}(\_f, hpos);$ $\mathtt{HPUT8}(\_f);$
  }

1757.   Definitions are written to the output only if they differ from HiTEX's built in defaults.

⟨ Output integer definitions 1757 ⟩ ≡
  $\mathtt{DBG}(\mathtt{DBGDEF}, \texttt{"Maximum\_int\_reference:\_\%d\textbackslash n"}, max\_ref[int\_kind]);$
  for $(i \leftarrow max\_fixed[int\_kind] + 1;\ i \leq max\_default[int\_kind];\ i{+}{+})$ {
    if $(int\_defined[i] \neq int\_defaults[i])$
      $\mathtt{HPUTDEF}(hput\_int(int\_defined[i]), i);$
  }
  for $(\ ;\ i \leq max\_ref[int\_kind];\ i{+}{+})$
    $\mathtt{HPUTDEF}(hput\_int(int\_defined[i]), i);$
This code is used in section 1750.

1758.   Dimensions.   We proceed as we did for integers, starting with the array that holds the defined dimensions.

⟨ HiTEX variables 1718 ⟩ +≡
  static scaled $dimen\_defined[^\#100] \leftarrow \{0\}$;

1759.   ⟨ HiTEX variables 1718 ⟩ +≡

  }

This code is used in section 1750.

1768. Glues.   In general there are two choices on how to store a definition: We can use the data structures used by TEX or we can use the data structures defined by HINT. If we are lucky, both of them are the same as we have seen for integers and dimensions. For extended dimensions, we had to use the HINT data type **Xdimen** because TEX has no corresponding data type and uses only reference numbers. In the case of glue, we definitely have a choice. We decide to use TEX's pointers to glue specifications in the hope to save some work when comparing glues for equality, because TEX already reuses glue specifications and often a simple comparison of pointers might suffice.

⟨ HiTEX variables 1718 ⟩ +≡
    static pointer $glue\_defined[^\#100]$;

1769.   ⟨ HiTEX variables 1718 ⟩ +≡
    static int $hmap\_glue[\,] \leftarrow \{$
        $line\_skip\_no$,   ▷ $line\_skip\_code$ 0 ◁
        $baseline\_skip\_no$,   ▷ $baseline\_skip\_code$ 1 ◁
        -1,   ▷ par_skip_code 2 ◁
        $above\_display\_skip\_no$,   ▷ $above\_display\_skip\_code$ 3 ◁
        $below\_display\_skip\_no$,   ▷ $below\_display\_skip\_code$ 4 ◁

    $\}$;

1770.   ⟨ Fix definitions for glue parameters 1770 ⟩ ≡
    $glue\_defined[zero\_skip\_no] \leftarrow zero\_glue$; $incr(glue\_ref\_count(zero\_glue))$;
    for $(i \leftarrow line\_skip\_code$; $i \leq par\_fill\_skip\_code$; $i{+}{+})$
        if $(hmap\_glue[i] \geq 0)$ {
            $glue\_defined[hmap\_glue[i]] \leftarrow glue\_par(i)$; $incr(glue\_ref\_count(glue\_par(i)))$;
        }
    $max\_ref[glue\_kind] \leftarrow$ MAX_GLUE_DEFAULT;
This code is used in section 1748.

1771. Next we define some auxiliary routines to compare glues for equality and to convert glues between the different representations.

⟨ HiTeX auxiliary routines 1703 ⟩ +≡

  static int $glue\_spec\_equal(\textbf{pointer } p, \textbf{pointer } q)$
  {
    return $(width(q) \equiv width(p) \land stretch(q) \equiv stretch(p) \land shrink(q) \equiv shrink(p) \land (stretch\_order(q) \equiv$
      $stretch\_order(p) \lor stretch(q) \equiv 0) \land (shrink\_order(q) \equiv shrink\_order(p) \lor shrink(q) \equiv 0));$
  }
  static int $glue\_equal(\textbf{pointer } p, \textbf{pointer } q)$
  {
    return $p \equiv q \lor glue\_spec\_equal(p, q);$
  }
  static int $Glue\_equal(\textbf{Glue } *p, \textbf{Glue } *q)$
  {
    return $(p{\to}w.w \equiv q{\to}w.w \land p{\to}w.h \equiv q{\to}w.h \land p{\to}w.v \equiv q{\to}w.v \land p{\to}p.f \equiv q{\to}p.f \land p{\to}m.f \equiv$
      $q{\to}m.f \land (p{\to}p.o \equiv q{\to}p.o \lor p{\to}p.f \equiv 0.0) \land (p{\to}m.o \equiv q{\to}m.o \lor q{\to}m.f \equiv 0.0));$
  }

1772. To find a matching glue we make two passes over the defined glues: on the first pass we just compare pointers and on the second pass we also compare values. An alternative approach to speed up searching is used for parameter lists as described below.

⟨ HiTeX auxiliary routines 1703 ⟩ +≡

  static int $hget\_glue\_no(\textbf{pointer } p)$
  {
    static int $rover \leftarrow 0;$
    int $i;$
    if $(p \equiv zero\_glue)$ **return** $zero\_skip\_no;$
    for $(i \leftarrow 0;\ i \leq max\_ref[glue\_kind];\ i{+}{+})$ {
      if $(p \equiv glue\_defined[rover])$ **return** $rover;$
      else if $(rover \equiv 0)$ $rover \leftarrow max\_ref[glue\_kind];$
      else $rover{-}{-};$
    }
    for $(i \leftarrow 0;\ i \leq max\_ref[glue\_kind];\ i{+}{+})$ {
      pointer $q \leftarrow glue\_defined[rover];$
      if $(glue\_spec\_equal(p, q))$ **return** $rover;$
      else if $(rover \equiv 0)$ $rover \leftarrow max\_ref[glue\_kind];$
      else $rover{-}{-};$
    }
    if $(max\_ref[glue\_kind] < {}^{\#}\text{FF} \land section\_no \equiv 2)$ {
      $rover \leftarrow {+}{+}max\_ref[glue\_kind];$ $glue\_defined[rover] \leftarrow p;$ $incr(glue\_ref\_count(p));$
      $\text{DBG}(\text{DBGDEF}, \text{"Defining}_{\sqcup}\text{new}_{\sqcup}\text{glue}_{\sqcup}\text{\%d\textbackslash n"}, rover);$ **return** $rover;$
    }
    else return $-1;$
  }

1773. ⟨Output glue definitions 1773⟩ ≡
  DBG(DBGDEF, "Maximum␣glue␣reference:␣%d\n", $max\_ref\,[glue\_kind]$);
  for ($i \leftarrow max\_fixed\,[glue\_kind] + 1;\ i \leq max\_default\,[glue\_kind];\ i\text{++}$) {
    Glue g;
    $to\_Glue\,(glue\_defined\,[i], \&g)$;
    if ($\neg Glue\_equal\,(\&g, \&glue\_defaults\,[i])$) HPUTDEF($hput\_glue\,(\&g), i$);
  }
  for (; $i \leq max\_ref\,[glue\_kind];\ i\text{++}$) HPUTDEF($hout\_glue\_spec\,(glue\_defined\,[i]), i$);
This code is used in section 1750.

1774.   The above code uses the following conversion routine. While HINT supports glue that depends on hsize and vsize, this is currently not supported by HiTeX. Future versions of HiTeX should extend glue spec nodes (and kern nodes) by fields for *hfactor* and *vfactor* which are zero by default. This would leave most parts of TeX unchanged. As a work-around one can combine a box with an extended dimension with a regular glue or kern.

⟨HiTeX auxiliary routines 1703⟩ +≡
  static void to_Glue(**pointer** p, **Glue** $*g$)
  {
    $g{\rightarrow}w.w \leftarrow width\,(p);\ g{\rightarrow}w.h \leftarrow g{\rightarrow}w.v \leftarrow 0.0;\ g{\rightarrow}p.f \leftarrow stretch\,(p)/(\textbf{double})\,\texttt{ONE};$
    $g{\rightarrow}p.o \leftarrow stretch\_order\,(p);\ g{\rightarrow}m.f \leftarrow shrink\,(p)/(\textbf{double})\,\texttt{ONE};\ g{\rightarrow}m.o \leftarrow shrink\_order\,(p);$
  }

1775.   Baseline Skips.   TeX's baseline nodes just store a baseline skip reference number. We have seen this situation before when dealing with extended dimensions and the solution here is the same: a dynamically allocated array.

⟨HiTeX variables 1718⟩ +≡
  typedef struct {
    pointer ls, bs;   ▷ line skip and baselineskip gluespecs ◁
    scaled lsl;   ▷ lineskip limit ◁
  } **bl_definition**;
  static bl_definition $*bl\_defined \leftarrow \Lambda$;
  static int $bl\_used \leftarrow 0, bl\_allocated \leftarrow 0$;

1776.   The zero baseline skip is predefined which prevents an ambiguous info value of zero in a baseline node.

⟨Initialize definitions for baseline skips 1776⟩ ≡
  $bl\_allocated \leftarrow 8$; $\texttt{ALLOCATE}(bl\_defined, bl\_allocated, \textbf{bl\_definition})$;
  $bl\_defined[zero\_baseline\_no].bs \leftarrow zero\_glue$; $incr(glue\_ref\_count(zero\_glue))$;
  $bl\_defined[zero\_baseline\_no].ls \leftarrow zero\_glue$; $incr(glue\_ref\_count(zero\_glue))$;
  $bl\_defined[zero\_baseline\_no].lsl \leftarrow 0$; $bl\_used \leftarrow \texttt{MAX\_BASELINE\_DEFAULT} + 1$;
  $max\_ref[baseline\_kind] \leftarrow \texttt{MAX\_BASELINE\_DEFAULT}$;
This code is used in section 1749.

1777.   ⟨HiTeX auxiliary routines 1703⟩ +≡
  static int $hget\_baseline\_no(\textbf{pointer}\ bs, \textbf{pointer}\ ls, \textbf{scaled}\ lsl)$
  {
    static int $rover \leftarrow 0$;
    int i;
    for $(i \leftarrow 0;\ i < bl\_used;\ i{+}{+})$ ▷ search for an existing spec ◁
    {
      bl_definition $*q \leftarrow \&(bl\_defined[rover])$;
      if $(glue\_equal(bs, q \rightarrow bs) \wedge glue\_equal(ls, q \rightarrow ls) \wedge lsl \equiv q \rightarrow lsl)$ **return** $rover$;
      else if $(rover \equiv 0)$ $rover \leftarrow bl\_used - 1$;
      else $rover{-}{-}$;
    }
    if $(bl\_used \geq bl\_allocated)$ $\texttt{RESIZE}(bl\_defined, bl\_allocated, \textbf{bl\_definition})$;
    $rover \leftarrow bl\_used{+}{+}$;
    if $(rover < {^\#}100 \wedge section\_no \equiv 2)$ $max\_ref[baseline\_kind] \leftarrow rover$;
    if $(glue\_equal(bs, zero\_glue))$ {
      $bl\_defined[rover].bs \leftarrow zero\_glue$; $incr(glue\_ref\_count(zero\_glue))$;
    }
    else {
      $bl\_defined[rover].bs \leftarrow bs$; $incr(glue\_ref\_count(bs))$;
    }
    if $(glue\_equal(ls, zero\_glue))$ {
      $bl\_defined[rover].ls \leftarrow zero\_glue$; $incr(glue\_ref\_count(zero\_glue))$;
    }
    else {
      $bl\_defined[rover].ls \leftarrow ls$; $incr(glue\_ref\_count(ls))$;
    }
    $bl\_defined[rover].lsl \leftarrow lsl$; **return** $rover$;
  }

1778.   The following routine does not allocate a new glue definition, because the baseline definitions are output after the glue definitions. This is not perfect.

⟨HiTEX auxiliary routines 1703⟩ +≡

```
static uint8_t hout_glue_spec(pointer p);

static uint8_t hout_baselinespec(int n)
{
    Info i ← b000;
    pointer p;
    scaled s;
    s ← bl_defined[n].lsl;
    if (s ≠ 0) {
        HPUT32(s); i |= b001;
    }
    p ← bl_defined[n].bs;
    if (p ≠ zero_glue) {
        uint8_t *pos;
        uint8_t tag;
        HPUTNODE;       ▷ allocate ◁
        pos ← hpos; hpos ++;     ▷ tag ◁
        tag ← hout_glue_spec(p); *pos ← tag; DBGTAG(tag, pos); DBGTAG(tag, hpos); HPUT8(tag);
        i |= b100;
    }
    p ← bl_defined[n].ls;
    if (p ≠ zero_glue) {
        uint8_t *pos;
        uint8_t tag;
        HPUTNODE;       ▷ allocate ◁
        pos ← hpos; hpos ++;     ▷ tag ◁
        tag ← hout_glue_spec(p); *pos ← tag; DBGTAG(tag, pos); DBGTAG(tag, hpos); HPUT8(tag);
        i |= b010;
    }
    return TAG(baseline_kind, i);
}
```

1779.   ⟨Output baseline skip definitions 1779⟩ ≡

```
DBG(DBGDEF, "Defining␣%d␣baseline␣skips\n", max_ref[baseline_kind]);
for (i ← 1; i ≤ max_ref[baseline_kind]; i++) {
    uint32_t pos ← hpos − hstart;
    uint8_t tag;
    hpos ++;       ▷ space for the tag ◁
    HPUT8(i);      ▷ reference ◁
    tag ← hout_baselinespec(i); hstart[pos] ← tag; HPUT8(tag);
}
```

This code is used in section 1750.

1780.   The following function is needed in HiTEX to produce debugging output if needed.

⟨ HiTEX routines 1696 ⟩ +≡

  static void *print_baseline_skip*(**int** *i*)
  {
    if $(0 \leq i \wedge i < bl\_used)$ {
      print_spec(*bl_defined*[*i*].*bs*, 0); *print_char*(','); *print_spec*(*bl_defined*[*i*].*ls*, 0); *print_char*(',');
      print_scaled(*bl_defined*[*i*].*lsl*);
    }
    else *print*("unknown");
  }

1781.   Discretionary breaks.   For discretionary breaks, we use again the pointer representation.

⟨ HiTEX variables 1718 ⟩ +≡
  static pointer $dc\_defined[^\#100]$;

1782.   There are no predefined discretionary breaks and so we start with three auxiliary functions and the function to get a "disc" number.

  The first two routines are used to compare discretionary breaks in order to reuse already defined disc numbers. The pre and post break lists must consist entirely of character, kern, box, rule, and ligature nodes. Unfortunately a box node might contain all kinds of nodes and its content might be huge and deeply nested. The following routine will not make a complete comparison but will give up if the box content is "too complex".

⟨ HiTEX auxiliary routines 1703 ⟩ +≡
  static bool $list\_equal(\textbf{pointer } p, \textbf{pointer } q)$;

  static bool $node\_equal(\textbf{pointer } p, \textbf{pointer } q)$
  {
    if $(is\_char\_node(p) \wedge is\_char\_node(q) \wedge font(p) \equiv font(q) \wedge character(p) \equiv character(q))$ **return** $true$;
    if $(\neg is\_char\_node(p) \wedge \neg is\_char\_node(q))$ {
      if $(type(p) \neq type(q))$ **return** $false$;
      if $(type(p) \equiv kern\_node \wedge subtype(p) \equiv subtype(q) \wedge width(p) \equiv width(q))$ **return** $true$;
      if $(type(p) \equiv ligature\_node \wedge character(lig\_char(p)) \equiv character(lig\_char(q)) \wedge font(lig\_char(p)) \equiv$
          $font(lig\_char(q)))$ **return** $true$;
      if $(type(p) \equiv rule\_node \wedge width(p) \equiv width(q) \wedge height(p) \equiv height(q) \wedge depth(p) \equiv depth(q))$
        return $true$;
      if $((type(p) \equiv hlist\_node \vee type(p) \equiv vlist\_node) \wedge width(p) \equiv width(q) \wedge height(p) \equiv$
          $height(q) \wedge depth(p) \equiv depth(q) \wedge shift\_amount(p) \equiv shift\_amount(q) \wedge glue\_sign(p) \equiv$
          $glue\_sign(q) \wedge glue\_order(p) \equiv glue\_order(q) \wedge glue\_set(p) \equiv glue\_set(q) \wedge list\_equal(list\_ptr(p),$
          $list\_ptr(q)))$ **return** $true$;
    }
    return $false$;
  }
  static bool $list\_equal(\textbf{pointer } p, \textbf{pointer } q)$
  { **loop** {
      if $(p \equiv q)$ **return** $true$;
      if $(p \equiv null \vee q \equiv null)$ **return** $false$;
      if $(\neg node\_equal(p, q))$ **return** $false$;
      $p \leftarrow link(p);\ q \leftarrow link(q)$;
    }
  }
  static pointer $copy\_disc\_node(\textbf{pointer } p)$
  {
    pointer q;
    $q \leftarrow get\_node(small\_node\_size);\ pre\_break(q) \leftarrow copy\_node\_list(pre\_break(p))$;
    $post\_break(q) \leftarrow copy\_node\_list(post\_break(p));\ type(q) \leftarrow type(p);\ subtype(q) \leftarrow subtype(p)$;
      ▷ replace count and explicit bit ◁
    return q;
  }

1783.   ⟨HiTEX routines 1696⟩ +≡

  static int $hget\_disc\_no(\textbf{pointer } p)$

  {

    static int $rover \leftarrow 0$;

    int i;

    for $(i \leftarrow 0;\ i \leq max\_ref[disc\_kind];\ i{+}{+})$ {

      pointer $q \leftarrow dc\_defined[rover]$;

      if $(is\_auto\_disc(p) \equiv is\_auto\_disc(q) \wedge replace\_count(p) \equiv replace\_count(q) \wedge list\_equal(pre\_break(p),$
          $pre\_break(q)) \wedge list\_equal(post\_break(p), post\_break(q)))$ **return** $rover$;

      else if $(rover \equiv 0)$ $rover \leftarrow max\_ref[disc\_kind]$;

      else $rover{-}{-}$;

    }

    if $(max\_ref[disc\_kind] \geq {}^{\#}\text{FF} \vee section\_no \neq 2)$ **return** -1;

    $rover \leftarrow {+}{+}max\_ref[disc\_kind];\ dc\_defined[rover] \leftarrow copy\_disc\_node(p)$;

    ⟨Allocate font numbers for glyphs in the pre- and post-break lists 1784⟩

    return $rover$;

  }

1784.   When we allocate disc numbers we might have fonts inside the pre- or post-break list, that never show up anywhere else in the content. These fonts would then be undefined once we start the definition section. So we have to make sure, all necessary fonts get defined.

⟨Allocate font numbers for glyphs in the pre- and post-break lists 1784⟩ ≡

  $ensure\_font\_no(pre\_break(p));\ ensure\_font\_no(post\_break(p))$;

This code is used in section 1783.

1785.   ⟨Output discretionary break definitions 1785⟩ ≡

  $\text{DBG}(\text{DBGDEF}, \texttt{"Maximum}_\sqcup\texttt{disc}_\sqcup\texttt{reference:}_\sqcup\texttt{\%d\textbackslash n"}, max\_ref[disc\_kind])$;

  for $(i \leftarrow 0;\ i \leq max\_ref[disc\_kind];\ i{+}{+})$ $\text{HPUTDEF}(hout\_disc(dc\_defined[i]), i)$;

This code is used in section 1750.

1786. Parameter Lists.   We store predefined parameter lists in a hash table in order to speed up
finding existing parameter lists. The parameter list itself is stored as a byte sequence using the short HINT
file format. We link the table entries in order of increasing reference numbers to be able to output them in
a more "orderly" fashion.

⟨ HiTEX variables 1718 ⟩ +≡
#**define** PLH_SIZE 313   ▷ a prime number $\approx 2^8 \times 1.2$. ◁
  static struct {
    int l;   ▷ link ◁
    uint32_t h;   ▷ hash ◁
    uint32_t n;   ▷ number ◁
    uint32_t s;   ▷ size ◁
    uint8_t $*p$;   ▷ pointer ◁
  } $pl\_defined$[PLH_SIZE] ← {{0}};
  static int pl_head ← 0, $*pl\_tail$ ← &pl_head;

1787.   Next we define three short auxiliary routines and the *hget_param_list_no* function.

⟨HiTeX routines 1696⟩ +≡

```
static uint32_t hparam_list_hash(List *l)
{
   uint32_t h ← 0;
   uint32_t i;
   for (i ← 0; i < l→s; i++) h ← 3 * h + hstart[l→p + i];
   return h;
}
static bool pl_equal(List *l, uint8_t *p)
{
   uint8_t *q ← hstart + l→p;
   uint32_t i;
   for (i ← 0; i < l→s; i++)
      if (q[i] ≠ p[i]) return false;
   return true;
}
static void pl_copy(List *l, uint8_t *p)
{
   uint8_t *q ← hstart + l→p;
   memcpy(p, q, l→s);
}
static int hget_param_list_no(List *l)
{
   uint32_t h;
   int i;
   if (l→s ≤ 0) return 0;
   h ← hparam_list_hash(l);  i ← h % PLH_SIZE;
   while (pl_defined[i].p ≠ Λ) {
      if (pl_defined[i].h ≡ h ∧ pl_equal(l, pl_defined[i].p)) return pl_defined[i].n;
      i ← i + 199;      ▷ some other prime ◁
      if (i ≥ PLH_SIZE) i ← i − PLH_SIZE;
   }
   if (max_ref[param_kind] ≥ #FF ∨ section_no ≠ 2) return −1;
   pl_defined[i].n ← ++max_ref[param_kind];  *pl_tail ← i;  pl_tail ← &(pl_defined[i].l);
   pl_defined[i].l ← 0;  pl_defined[i].h ← h;  pl_defined[i].s ← l→s;
   ALLOCATE(pl_defined[i].p, l→s, uint8_t);  pl_copy(l, pl_defined[i].p);  return pl_defined[i].n;
}
```

1788.   To output parameter lists, we need a function to output a parameter node:

⟨ HiTEX routines 1696 ⟩ +≡
```
static void hdef_param_node(int ptype, int pnumber, int pvalue)
{
    if (ptype ≡ int_type) {
        if (pvalue ≡ int_defined[hmap_int[pnumber]]) return;
        else HPUTDEF(hput_int(pvalue), hmap_int[pnumber]);
    }
    else if (ptype ≡ dimen_type) {
        if (pvalue ≡ dimen_defined[hmap_dimen[pnumber]]) return;
        else HPUTDEF(hput_dimen(pvalue), hmap_dimen[pnumber]);
    }
    else if (ptype ≡ glue_type) {
        if (glue_equal(pvalue, glue_defined[hmap_glue[pnumber]])) return;
        else HPUTDEF(hout_glue_spec((pointer) pvalue), hmap_glue[pnumber]);
    }
    else QUIT("Unexpected␣parameter␣type␣%d", ptype);
}
```

1789.   Now we use the linked list starting with *pl_head* to output the predefined parameter lists sorted by their reference number.

⟨ Output parameter list definitions 1789 ⟩ ≡
```
DBG(DBGDEF, "Defining␣%d␣parameter␣lists\n", max_ref[param_kind]);
for (i ← pl_head; i > 0; i ← pl_defined[i].l) {
    int j, k;
    DBG(DBGDEF, "Defining␣parameter␣list␣%d,␣size␣0x%x\n", i, pl_defined[i].s);
    j ← hsize_bytes(pl_defined[i].s); HPUTX(1 + 1 + j + 1 + pl_defined[i].s + 1 + j + 1);
    if (j ≡ 4) k ← 3;
    else k ← j;
    HPUTTAG(param_kind, k); HPUT8(pl_defined[i].n); hput_list_size(pl_defined[i].s, j); HPUT8(#100 − k);
    memcpy(hpos, pl_defined[i].p, pl_defined[i].s); hpos ← hpos + pl_defined[i].s; HPUT8(#100 − k);
    hput_list_size(pl_defined[i].s, j); HPUTTAG(param_kind, k);
}
```
This code is used in section 1750.

1790.   Fonts.   To store a font definition, we define the data type **Font** and an array *hfonts* of pointers indexed by HINT font numbers. To map HINT font numbers to TEX font numbers, the **Font** contains the i field; to map TEX font numbers to HINT font numbers, we use the array *hmap_font*.

⟨ HiTEX variables 1718 ⟩ +≡
#**define** `MAX_FONTS` #100
  typedef struct {
    uint8_t i;   ▷ the TEX font number ◁
    pointer g;   ▷ space glue ◁
    pointer h;   ▷ default hyphen ◁
    pointer p[`MAX_FONT_PARAMS`];   ▷ font parameters ◁
    uint16_t m;   ▷ section number of font metric file ◁
    uint16_t y;   ▷ section number of font glyph file ◁
  } **Font**;
  static Font ∗*hfonts*[`MAX_FONTS`] ← {Λ};
  static int *hmap_font*[`MAX_FONTS`];

1791.   ⟨ Initialize definitions for fonts 1791 ⟩ ≡
  for (i ← 0; i < #100; i++) *hmap_font*[i] ← −1;
  max_ref[*font_kind*] ← −1;

This code is used in section 1749.

1792.   Allocation of a **Font** record takes place when we translate a TeX font number to a HINT font number using the function *hget_font_no*, and while doing so discover that the corresponding HINT font number does not yet exist. Because the **Font** structure must be initialized after allocating it, we start with some auxiliary routines for that purpose.

⟨HiTeX auxiliary routines 1703⟩ +≡

  static pointer *find_space_glue*(**internal_font_number** *f*)

  { **font_index** *main_k*;

    pointer *main_p* ← *font_glue*[*f*];

  {   ▷ used only for texts ◁

  }

1793.   In the following code, f is a TEX internal font number and g is the corresponding HINT font number. TEX's null-font, a kind of undefined font containing no characters is replaced by HINT's font number zero. Actually the nullfont should never appear in the output, but if it does so, either an error message or a more sensible replacement font might be in order.

Finding the right font file based on the name of the name of the `.tfm` file might require finding a `.map` file using $kpse\_find\_file(name, kpse\_fontmap\_format, false)$. This is currently not implemented.

⟨ HiTEX auxiliary routines 1703 ⟩ +≡

```
  static char *hfind_glyphs(char *filename)
  {
    char *fname ← Λ;

    kpse_glyph_file_type file_ret;  fname ← kpse_find_file(filename, kpse_type1_format, true);

    g ← ++(max_ref[font_kind]); ALLOCATE(hfonts[g], 1, Font); hfonts[g]→i ← f; hmap_font[f] ← g;
    hfonts[g]→g ← hget_font_space(f); hfonts[g]→h ← hget_font_hyphen(f);
    pack_file_name(font_name[f], empty_string, empty_string, ".tfm");
    n ← kpse_find_tfm((char *) name_of_file + 1);
    if (n ≡ Λ) QUIT("Unable␣to␣find␣.tfm␣file␣for␣font␣%s", (char *) name_of_file + 1);
    hfonts[g]→m ← hnew_file_section(n);  free(n);
    pack_file_name(font_name[f], empty_string, empty_string, "");
    n ← hfind_glyphs((char *) name_of_file + 1);
    if (n ≡ Λ) QUIT("Unable␣to␣find␣glyph␣file␣for␣font␣%s", (char *) name_of_file + 1);
    hfonts[g]→y ← hnew_file_section(n);  free(n); return g;
  }
```

1794.   Surprisingly, not all characters that occur in a HINT file are inside the content section; some characters might hide in the definition section inside the pre- or post-break list of a predefined discretionary break. To make sure that the fonts necessary for these characters are included in the final HINT file, we check these lists to make sure all TEX font numbers have a corresponding HINT font number.

⟨ HiTEX auxiliary routines 1703 ⟩ +≡
```
static void ensure_font_no(pointer p)
{
    while (p ≠ null) {
        if (is_char_node(p)) hget_font_no(font(p));
        else if (type(p) ≡ hlist_node ∨ type(p) ≡ vlist_node) ensure_font_no(list_ptr(p));
        p ← link(p);
    }
}
```

1795.   ⟨ Output font definitions 1795 ⟩ ≡
```
{
    int f;
    DBG(DBGDEF, "Defining␣%d␣fonts\n", max_ref[font_kind] + 1);
    for (f ← 0; f ≤ max_ref[font_kind]; f++) {
        Font *hf ← hfonts[f];
        internal_font_number g ← hf →i;
        uint32_t pos ← hpos − hstart;
        Info i ← b000;
        DBG(DBGDEF, "Defining␣font␣%d␣size␣0x%x\n", f, font_size[g]); hpos ++; HPUTNODE;
            ▷ space for the tag and the node ◁
        HPUT8(f);      ▷ reference ◁

        HPUTCONTENT(hout_disc, hf →h); hdef_font_params(hf →p);
        DBG(DBGDEF, "End␣of␣font␣%d\n", f); hput_tags(pos, TAG(font_kind, i));
    }
}
```
This code is used in section 1750.

1796.   We used the following function to write a TEX string to the HINT file:

⟨ HiTEX auxiliary routines 1703 ⟩ +≡

```
static void hout_string(int s)
{
    pool_pointer j;
    uint8_t c;

    j ← str_start[s];
    while (j < str_start[s + 1]) {
        c ← so(str_pool[j++]);
        if (c ≡ '%' ∨ c < #20 ∨ c ≥ #7F) {
            char str[4];

            snprintf(str, 4, "%%%02X", c);      ▷ convert to printable ASCII ◁
            HPUTX(3); HPUT8(str[0]); HPUT8(str[1]); HPUT8(str[2]);
        }
        else {
            HPUTX(1); HPUT8(c);
        }
    }
    HPUT8(0);
}
```

1797.   We used the following macro to add tags around the font glue and the font hyphen:

⟨ HiTEX macros 1744 ⟩ +≡
#**define** HPUTCONTENT(F, D)

```
{
    uint32_t _p;
    uint8_t _f;

    HPUTNODE;       ▷ allocate ◁
    _p ← hpos ++ − hstart;       ▷ tag ◁
    _f ← F(D); *(hstart + _p) ← _f; DBGTAG(_f, hstart + _p); DBGTAG(_f, hpos); HPUT8(_f);
}
```

1798.   Labels.   The only label that must always exist is the zero label. It is used to mark the "home" position of a document.

We allocate the zero label with the first call to *next_label* and initialize it with the value from *label_defaults*. We then make sure it can be found under the name "HINT.home".

⟨ Initialize definitions for labels 1798 ⟩ ≡
```
{
    char nom[] ← "HINT.home";
    unsigned int h ← name_hash(nom) % LABEL_HASH;
    int i ← insert_hash(h, 0, nom);

    if (i ≠ zero_label_no) QUIT("Trying␣to␣allocate␣the␣zero␣label,␣got␣%d", i);
    labels[zero_label_no] ← label_defaults[zero_label_no];  labels[zero_label_no].next ← first_label;
    first_label ← zero_label_no;
    DBG(DBGLABEL, "Defining␣zero␣label:␣pos=0x%x\n", labels[zero_label_no].pos);
}
```
This code is used in section 1749.

1799. Page Templates.
    Once we start producing content nodes, we update the maximum numbers of page templates and streams from *max_page* and *max_stream*. These values might have changed because templates were loaded from a format file.

⟨ Fix definitions of page templates 1799 ⟩ ≡
    max_ref [*page_kind*] ← *max_page*; *max_ref* [*stream_kind*] ← *max_stream*;
This code is used in section 1748.

1800.   As part of a page template, we will see stream insertion nodes. When we encounter an *stream_node* inside a template definition, we output a stream insertion point.

⟨ cases to output whatsit content nodes 1800 ⟩ ≡
case *stream_node*: HPUT8(*setstream_number*(*p*)); *tag* ← TAG(*stream_kind*, *b100*); **break**;
See also sections 1810, 1826, 1827, 1828, 1829, 1830, 1831, 1839, and 1840.
This code is used in section 1825.

1801.   ⟨ Output page template definitions 1801 ⟩ ≡
  DBG(DBGDEF, "Maximum␣page␣template␣reference:␣%d\n", *max_page*);
  {
    pointer *t*;
    for (*t* ← *link*(*setpage_head*); *t* ≠ *null*; *t* ← *link*(*t*)) {
      uint32_t *pos* ← *hpos* − *hstart*;

      DBG(DBGDEF, "Defining␣page␣template␣%d\n", *setpage_number*(*i*));
      hpos ++; HPUTNODE;   ▷ space for the tag and the node ◁
      HPUT8(*setpage_number*(*t*)); *hout_string*(*setpage_name*(*t*)); HPUT8(*setpage_priority*(*t*));
      hout_glue_node(*setpage_topskip*(*t*)); *hput_dimen*(*setpage_depth*(*t*));
      hout_xdimen_node(*setpage_height*(*t*)); *hout_xdimen_node*(*setpage_width*(*t*));
      hout_list_node2(*setpage_list*(*t*)); ⟨output stream definitions 1802 ⟩
      hput_tags(*pos*, TAG(*page_kind*, 0));
    }
  }
This code is used in section 1750.

1802.   As part of the output of page template definitions, we output stream definitions:

⟨ output stream definitions 1802 ⟩ ≡
  {
    pointer p, q;
    $p \leftarrow setpage\_streams(t)$;
    while $(p \neq null)$ {
      uint8_t n;

      $n \leftarrow setstream\_number(p)$; DBG(DBGDEF, "Defining␣stream␣%d␣at␣"SIZE_F"\n", $n, hpos - hstart$);
      HPUTTAG($stream\_kind, b100$); HPUT8(n); $hout\_xdimen\_node(setstream\_max(p))$;
        ▷ maximum height ◁
      HPUT16($setstream\_mag(p)$);   ▷ factor ◁
      HPUT8($setstream\_preferred(p)$);   ▷ preferred ◁
      HPUT8($setstream\_next(p)$);   ▷ next ◁
      HPUT16($setstream\_ratio(p)$);   ▷ ratio ◁
      $q \leftarrow setstream\_before(p)$; $setstream\_before(p) \leftarrow null$; $hout\_list\_node2(q)$; $flush\_node\_list(q)$;
      $hout\_xdimen\_node(setstream\_width(p))$; $q \leftarrow setstream\_topskip(p)$; $hout\_glue\_node(q)$;
      $delete\_glue\_ref(q)$; $q \leftarrow setstream\_after(p)$; $setstream\_after(p) \leftarrow null$; $hout\_list\_node2(q)$;
      $flush\_node\_list(q)$; $q \leftarrow setstream\_height(p)$; $hout\_glue\_node(q)$; $delete\_glue\_ref(q)$;
      HPUTTAG($stream\_kind, b100$); $p \leftarrow link(p)$;
    }
  }

This code is used in section 1801.

1803.   HINT Content.   TEX puts content nodes on the contribution list and once in a while calls *build_page* to move nodes from the contribution list to the current page. HiTEX has a special version of *build_page* that will simply remove nodes from the contribution list and passes them to the function *hout_node*. The actual output of HINT nodes is accomplished with functions defined in `put.c` (see Martin Ruckert, The HINT file format).

⟨HiTEX routines 1696⟩ +≡
  static void *hout_node*(**pointer** *p*)
  {
    uint32_t *pos* ← *hpos* − *hstart*;
    uint8_t *tag*;
    HPUTNODE; *hpos* ++;
    if (*is_char_node*(*p*)) ⟨output a character node 1804⟩
    else
      switch (*type*(*p*))
      {
        ⟨cases to output content nodes 1805⟩
        default:
          MESSAGE("\nOutput␣of␣node␣type=%d␣subtype=%d␣not␣implemented\n", *type*(*p*), *subtype*(*p*));
          hpos −−; **return**;
      }
    hput_tags(*pos*, *tag*);
  }

1804.   Characters.   The processing of a character node consist of three steps: checking for definitions, converting the TEX node pointed to by p to a HINT data type, here a *Glyph*, and using the corresponding hput_... function to output the node and return the *tag*. In the following, we will see the same approach in many small variations for all kinds of nodes.

⟨ output a character node 1804 ⟩ ≡
    {
        Glyph g; *g.f* ← *hget_font_no*(*font*(*p*)); *g.c* ← *character*(*p*); *tag* ← *hput_glyph*(&*g*);
    }

This code is used in section 1803.

1805.   Penalties.   Integer nodes, which as content nodes are used for penalties, come next. Except for the embedding between **case** and **break**, the processing of penalty nodes follows the same pattern we have just seen.

⟨ cases to output content nodes 1805 ⟩ ≡
case $penalty\_node$:
  {
    int n, i;
    $i \leftarrow penalty(p)$;
    if $(i > 10000)$ $i \leftarrow 10000$;
    else if $(i < -10000)$ $i \leftarrow -10000$;
    $n \leftarrow hget\_int\_no(i)$;
    if $(n < 0)$ $tag \leftarrow hput\_int(i)$;
    else {
      $\text{HPUT8}(n)$; $tag \leftarrow \text{TAG}(penalty\_kind, 0)$;
    }
  }
  break;

See also sections 1806, 1813, 1815, 1817, 1818, 1819, 1820, 1821, 1822, 1824, 1825, and 1834.

This code is used in section 1803.

1806.   Kerns.   The kern nodes of TEX contain a single dimension and a flag to mark "explicit" kerns.

⟨ cases to output content nodes 1805 ⟩ +≡

case *kern_node*:
  {
    int *n*;
    n ← *hget_dimen_no*(*width*(*p*));
    if (*n* < 0) {
      Kern *k*;
      k.x ← (*subtype*(*p*) ≡ *explicit*); *k.d.w* ← *width*(*p*); *k.d.h* ← *k.d.v* ← 0.0; *tag* ← *hput_kern*(&*k*);
    }
    else {
      HPUT8(*n*);
      if (*subtype*(*p*) ≡ *explicit*) *tag* ← TAG(*kern_kind*, *b100*);
      else *tag* ← TAG(*kern_kind*, *b000*);
    }
  }
  break;

1807.   Extended Dimensions.   Extended dimensions do not constitute content on their own, but nodes containing an extended dimension are part of other nodes. Here we define an auxiliary function that checks for a predefined extended dimension and if found outputs the reference number and returns false; otherwise it outputs the extended dimension and returns true.

⟨HiTeX auxiliary routines 1703⟩ +≡

```
static void hout_xdimen_node(pointer p)
{
    Xdimen x;
    x.w ← xdimen_width(p);  x.h ← xdimen_hfactor(p)/(double) ONE;
    x.v ← xdimen_vfactor(p)/(double) ONE;  hput_xdimen_node(&x);
}
static bool hout_xdimen(pointer p)
{
    int n ← hget_xdimen_no(p);
    if (n ≥ 0) {
        HPUT8(n); return false; }
    else {
        hout_xdimen_node(p); return true; }
}
```

1808. Languages. The *hlanguage* array maps the language numbers of TEX to HINT language numbers.

⟨ HiTEX variables 1718 ⟩ +≡

```
static struct {
    uint8_t n;
    str_number s;
} hlanguage[# 100];
```

1809. For any language number of TEX, the following function returns the corresponding HINT language number. Since TEX knows about a maximum of 255 languages, there is no need for overflow checking. The next function writes a language node to the output stream.

⟨ HiTEX auxiliary routines 1703 ⟩ +≡

```
static uint8_t hget_language_no(uint8_t n)
{
    int i;
    for (i ← 0; i ≤ max_ref[language_kind]; i++)
        if (hlanguage[i].n ≡ n) return i;
    i ← ++max_ref[language_kind]; hlanguage[i].n ← n; hlanguage[i].s ← 0;    ▷ language unknown ◁
    return i;
}
static uint8_t hout_language(uint8_t n)
{
    n ← hget_language_no(n);
    if (n < 7) return TAG(language_kind, n + 1);
    else {
        HPUT8(n); return TAG(language_kind, 0);
    }
}
```

1810. After these preparations, the output of a language node is simple:

⟨ cases to output whatsit content nodes 1800 ⟩ +≡

case *language_node*: *tag* ← *hout_language*(*what_lang*(*p*)); **break**;

1811. Normally TEX does not produce an initial language node and then the language in the HINT file would not be known until it changes for the first time.

⟨ insert an initial language node 1811 ⟩ ≡

```
{
    uint32_t pos ← hpos − hstart;
    hpos ++; hput_tags(pos, hout_language(language));
}
```

This code is used in section 1739.

1812. TEX offers currently no simple way to obtain a standardized language identifier for the current language. So if the string number of the language is zero, we output the string `"unknown"`; if somehow the language is known, we output the corresponding string from TEX's string pool.

⟨Output language definitions 1812⟩ ≡
    DBG(DBGDEF, `"Maximum␣language␣reference:␣%d\n"`, $max\_ref[language\_kind]$);
    for ($i \leftarrow max\_fixed[language\_kind] + 1$; $i \leq max\_ref[language\_kind]$; $i{+}{+}$) {
      HPUTNODE; HPUT8(TAG($language\_kind, 0$)); HPUT8(i);
      if ($hlanguage[i].s \equiv 0$) $hput\_string$(`"unknown"`);
      else $hout\_string(hlanguage[i].s)$;
      HPUT8(TAG($language\_kind, 0$));
    }

This code is used in section 1750.

1813.   Mathematics.   TEX's math nodes have an optional width—a copy of the mathsurround parameter—while HINT math nodes do not. Therefore we have to add an explicit kern node if the width is nonzero. We add it before a "math on" node or after a "math off" to get the same behavior in respect to line breaking.

⟨ cases to output content nodes 1805 ⟩ +≡

case $math\_node$:
  {
    Kern k;
    $k.x \leftarrow true$; $k.d.w \leftarrow width(p)$; $k.d.h \leftarrow k.d.v \leftarrow 0.0$;
    if $(subtype(p) \equiv before)$ {
      $tag \leftarrow \texttt{TAG}(math\_kind, b111)$;
      if $(width(p) \neq 0)$ {
        $hput\_tags(pos, hput\_kern(\&k))$; $pos \leftarrow hpos - hstart$; HPUTNODE; $hpos{+}{+}$;
      }
    }
    else {
      $tag \leftarrow \texttt{TAG}(math\_kind, b011)$;
      if $(width(p) \neq 0)$ {
        $hput\_tags(pos, tag)$; $pos \leftarrow hpos - hstart$; HPUTNODE; $hpos{+}{+}$; $tag \leftarrow hput\_kern(\&k)$;
      }
    }
  }
  break;

1814.   Glue and Leaders.   Because glue specifications and glue nodes are sometimes part of other nodes, we start with three auxiliary functions: The first simply converts a HiTEX glue node into a HINT **Glue**, outputs it and returns the tag; the second checks for predefined glues, and the third outputs a complete glue node including tags.

⟨HiTEX auxiliary routines 1703⟩ +≡
  static uint8_t *hout_glue_spec*(**pointer** *p*)
  { **Glue** *g*;
    to_Glue(*p*, &*g*); **return** *hput_glue*(&*g*); }
  static uint8_t *hout_glue*(**pointer** *p*)
  {
    int *n*;
    n ← *hget_glue_no*(*p*);
    if (*n* < 0) **return** *hout_glue_spec*(*p*);
    else { HPUT8(*n*); **return** TAG(*glue_kind*, 0); }
  }
  static void *hout_glue_node*(**pointer** *p*)
  {
    uint8_t *∗pos*;
    uint8_t *tag*;
    HPUTNODE;   ▷ allocate ◁
    pos ← *hpos*; *hpos* ++; ▷ tag ◁

1821. Adjustments.

⟨ cases to output content nodes 1805 ⟩ +≡
case *adjust_node*: *hout_list_node2*(*adjust_ptr*(*p*)); *tag* ← TAG(*adjust_kind*, 1); **break**;

1822.   Insertions.   TₑX's insertions are mapped to HINT streams.

⟨cases to output content nodes 1805⟩ +≡
case *ins_node*: ⟨output stream content 1823⟩
  break;

1823.   Here we consider stream content and come back to stream definitions in a later section. In a HINT stream content node the stream parameters *floating_penalty*, *split_max_depth*, and *split_top_skip* are optional. If omitted, the defaults from the stream definition are used. This is probably also for TₑX the most common situation. It is, however, possible to supply more than one page template with different defaults and while not very common, TₑX might change the parameters at any time. Because we don't know which is the current page template, it is not possible to compare the current parameter values against the defaults, and we have to supply all the parameters always. In a future version, we might have a TₑX primitive that allows us to signal "use the defaults".

⟨output stream content 1823⟩ ≡
  {

1824. Marks.   We currently ignore Marks.

⟨ cases to output content nodes 1805 ⟩ +≡
case *mark_node*: *hpos* −−; **return**;

1825.   Whatsit Nodes.   We have added custom whatsit nodes and now we switch based on the subtype.

⟨ cases to output content nodes 1805 ⟩ +≡
case *whatsit_node*:
  switch (*subtype*(*p*)) {
    ⟨ cases to output whatsit content nodes 1800 ⟩
    default:
      if (*subtype*(*p*) ≥ *hitex_ext*) {
        MESSAGE("\nOutput␣of␣whatsit␣nodes␣subtype=%d␣not␣implemented\n", *subtype*(*p*));
      }
      hpos −−;   ▷ remove tag ◁
      return;
    }
  break;

1826.   For TₑX's whatsit nodes that handle output files, no code is generated; hence, we call *out_what* and simply remove the tag byte that is already in the output. When the \write node arrives here, it is normally handled in *hlist_out* or *vlist_out* in an environment determined by the output routine. For example LᴬTₑX redefines \protect as \noexpand and these redefinitions need to be made before calling *out_what* which expands the token list. We should therefore add the definitions contained in the output routine to mimic expanding inside an output routine.

⟨ cases to output whatsit content nodes 1800 ⟩ +≡
case *open_node*: **case** *write_node*: **case** *close_node*: **case** *special_node*: **case** *latespecial_node*:
  out_what(*p*); *hpos* −−; **return**;

1827.   Paragraphs.   When we output a paragraph node, we have to consider a special case: The
parameter list is given by a reference number but the extended dimension needs an *xdimen* node. In
this case the reference number for the parameter list comes first, while otherwise the extended dimension
would come first. To determine whether there is a reference number for the parameter list, the function
hout_param_list is writing the parameter list to the output.

$\langle$ cases to output whatsit content nodes 1800 $\rangle$ +≡

1842.   HiTEX Limitations.

• Kerns and glues using a width that depends on `\hsize` or `\vsize` are not yet supported.

• Tables where the width of a column depends on `\hsize` or `\vsize` are not tested and probably not yet supported.

• `\vcenter` will not work if any dimension of the vertical list depends on `\hsize` or `\vsize`.

• The encoding of horizontal lists as texts is not yet supported, but it would make the HINT file shorter and much better to read when stretched into long HINT format.

1843.   System-dependent changes.   This section should be replaced, if necessary, by any special modifications of the program that are necessary to make TEX work at a particular installation. It is usually best to design your change file so that all changes to previous sections preserve the section numbering; then everybody's version will be consistent with the published program. More extensive changes, which introduce new sections, can be inserted here; then only the index itself will get a new section number.

1844. TEX Live Integration. A TEX engine that aspires to become a member of the TEX Live family of programs must

– respect the TEX Live conventions for command line parameters,
– find its input files using the `kpathsearch` library, and
– implement TEX primitives to support LATEX.

Naturally, the functions that follow here are taken, with small modifications, from the TEX Live sources. What is added here, or rather subtracted here, are the parts that are specific to some of the TEX engines included in TEX Live. New is also that the code is presented in literate programming style.

The code that follows is organized in three parts. Some code for TEX Live must come before the definition of TEX's macros because it uses include files containing identifiers that are in conflict with TEX's macros or modify these macros. For example TEX's *banner* is modified by adding the TEX Live version.

⟨ Header files and function declarations 9 ⟩ +≡
#ifdef WEB2CVERSION
#define TL_VERSION"(TeX␣Live␣"WEB2CVERSION ")"
#else
#define TL_VERSION
#endif

1845. The remaining two parts are first auxiliary functions and then those functions that are called from the "classic" TEX code.

⟨ TEX Live auxiliary functions 1849 ⟩
⟨ TEX Live functions 1847 ⟩

1846. Most of the code that we present next comes together in the function *main_init* which is the first function called in the main program of a TEX engine belonging to TEX Live. Before doing so, we make copies of argument count and argument vector putting them in global variables.

⟨ Global variables 13 ⟩ +≡
  static char ∗∗*argv*;
  static int *argc*;

1847. ⟨ TEX Live functions 1847 ⟩ ≡
  static void *main_init*(**int** *ac*, **char** ∗*av*[ ])
  { **char** ∗*main_input_file*;

    argc ← *ac*; *argv* ← *av*; *interaction* ← *error_stop_mode*; *kpse_record_input* ← *recorder_record_input*;
    kpse_record_output ← *recorder_record_output*; ⟨ parse options 1855 ⟩
    ⟨ set the program and engine name 1878 ⟩
    ⟨ activate configuration lines 1876 ⟩
    ⟨ set the input file name 1880 ⟩
    ⟨ set defaults from the `texmf.cfg` file 1881 ⟩
    ⟨ set the format name 1885 ⟩
    ⟨ enable the generation of input files 1893 ⟩
  }
See also sections 1853, 1889, and 1892.
This code is used in section 1845.

1848. ⟨ Forward declarations 52 ⟩ +≡
  static void *main_init*(**int** *ac*, **char** ∗*av*[ ]);

1849.   Command Line.   Let's begin with the beginning: the command line. To see how a command line is structured, we first look at the help text that is displayed if the user asks for it (or if T_EX decides that the user needs it). The help text is produced by the function *usage_help*.

⟨ T_EX Live auxiliary functions 1849 ⟩ ≡
  static void *usage_help*(**void**)
  { ⟨ explain the command line 1850 ⟩
    ⟨ explain the options 1851 ⟩
    fprintf(*stdout*,
        "\nFor further information and reporting bugs see https://hint.userweb.mwn.de/\n");
    exit(0);
  }

See also sections 1862, 1866, 1869, 1870, 1875, 1879, 1882, 1886, 1887, 1890, 1891, and 1896.

This code is used in section 1845.

1850.   The command line comes in three slightly different versions:

⟨ explain the command line 1850 ⟩ ≡
  fprintf(*stdout*,
  "Usage: %s [OPTION]... [TEXNAME[.tex]] [COMMANDS]\n"
  "   or: %s [OPTION]... \\FIRST-LINE\n"
  "   or: %s [OPTION]... &FMT ARGS\n\n",
  argv[0], *argv*[0], *argv*[0]);
  fprintf(*stdout*,
  " Run HiTeX on TEXNAME, creating TEXNAME.hnt.\n"
  " Any remaining COMMANDS are processed\n"
  " as TeX input after TEXNAME is read.\n"
  " If the first line of TEXNAME starts with %%&FMT, and FMT is\n"
  " an existing .fmt file, use it. Else use 'NAME.fmt', where\n"
  " NAME is the program invocation name.\n"
  "\n"
  " Alternatively, if the first non-option argument begins\n"
  " with a backslash, interpret all non-option arguments as\n"
  " a line of TeX input.\n"
  "\n"
  " Alternatively, if the first non-option argument begins\n"
  " with a &, the next word is taken as the FMT to read,\n"
  " overriding all else. Any remaining arguments are\n"
  " processed as above.\n"
  "\n"
  " If no arguments or options are specified, prompt for input.\n"
  "\n");

This code is used in section 1849.

1851.   Options.   Here is the list of possible options and their explanation:

⟨ explain the options 1851 ⟩ ≡
  fprintf (*stdout*, "Options:\n"
  " -help   "
      "\t display this help and exit\n"
  " -version   "
      "\t output version information and exit\n"
  " -etex   "
      "\t enable e-TeX extensions\n"
  " -ltx   "
      "\t enable LaTeX extensions, implies -etex\n"
  " -ini   "
      "\t be initex for dumping formats; this is\n"
      "\t\t\t also true if the program name is 'hinitex'\n"
  " -progname=STRING   "
      "\t set program (and fmt) name to STRING\n"
  " -fmt=FMTNAME   "
      "\t use FMTNAME instead of program name or a %%& line\n"
  " -output-directory=DIR "
      "\t use existing DIR as the directory to write files to\n"
  " -jobname=STRING   "
      "\t set the TeX \\jobname to STRING\n"
  " [-no]-mktex=FMT   "
      "\t disable/enable mktexFMT generation (FMT=tex/tfm/fmt/pk)\n"
  " -interaction=STRING   "
      "\t set interaction mode (STRING=batchmode/\n"
      "\t\t\t nonstopmode/scrollmode/errorstopmode)\n"
  " -kpathsea-debug=NUMBER"
      "\t set path searching debugging flags according\n"
      "\t\t\t to the bits of NUMBER\n"
  " -recorder"
      "\t\t enable filename recorder\n"
  " [-no]-parse-first-line"
      "\t disable/enable parsing of the first line of\n"
      "\t\t\t the input file\n"
  " [-no]-file-line-error"
      "\t disable/enable file:line:error style\n"

      "\t process STRING like a line in texmf.cnf\n"
  " -compress   "
      "\t enable compression of section 1 and 2\n"
  " [-no]-empty-page   "
      "\t disable/enable empty pages\n"
  " [-no]-hyphenate-first-word "
      "\t disable/enable hyphenation of\n"
      "\t\t\t the first word of a paragraph\n"
  " -resolution=NUMBER   "
      "\t set the resolution to NUMBER dpi\n"
  " -mfmode=MODE   "
      "\t set the METAFONT mode to MODE\n"
#**ifdef** DEBUG
  " -hint-debug=FLAGS   "

```
      "\t set flags to control hint debug output\n"
  " -hint-debug-help        "
      "\t give help on hint debugging\n"
#endif
  );
```

This code is used in section 1849.

1852. The processing of command line options is controlled by the *long_options* array. Each entry in this array contains first the name of the option, then a flag that tells whether the option takes an argument or not. If next the (optional) address of a flag variable is given, it is followed by the value to store in the flag variable. In this case, setting the flag variable is handled by the *getopt_long_only* function.

Besides the flag variables that occur in the table, a few string variables may be set using the options. The following is a complete list of these variables. Variables are initialized with -1 to indicate an undefined value; string variables are initialized with Λ.

⟨ Global variables 13 ⟩ +≡
    static int *iniversion* ← *false*, *etexp* ← *false*, *ltxp* ← *false*, *recorder_enabled* ← *false*;
    static int *parsefirstlinep* ← −1, *filelineerrorstylep* ← −1, *interaction_option* ← −1;
    static const char ∗*user_progname* ← Λ, ∗*output_directory* ← Λ, ∗*c_job_name* ← Λ, ∗*dump_name* ← Λ;

    static int *option_no_empty_page* ← *true*, *option_hyphen_first* ← *true*;
    static int *option_dpi* ← 600;
    static const char ∗*option_mfmode* ← "ljfour", ∗*option_dpi_str* ← "600";
    extern int *option_compress*;
    extern unsigned int *debugflags*;
    static struct *option long_options*[ ] ← {
        {"help", 0, 0, 0},
        {"version", 0, 0, 0},
        {"interaction", 1, 0, 0},
        {"mktex", 1, 0, 0},
        {"no-mktex", 1, 0, 0},
        {"kpathsea-debug", 1, 0, 0},
        {"progname", 1, 0, 0},
        {"fmt", 1, 0, 0},
        {"output-directory", 1, 0, 0},
        {"jobname", 1, 0, 0},
        {"cnf-line", 1, 0, 0},
        {"ini", 0, &*iniversion*, 1},
        {"etex", 0, &*etexp*, 1},
        {"ltx", 0, &*ltxp*, 1},
        {"recorder", 0, &*recorder_enabled*, 1},
        {"parse-first-line", 0, &*parsefirstlinep*, 1},
        {"no-parse-first-line", 0, &*parsefirstlinep*, 0},
        {"file-line-error", 0, &*filelineerrorstylep*, 1},
        {"no-file-line-error", 0, &*filelineerrorstylep*, 0},
        {"compress", 0, &*option_compress*, 1},
        {"no-empty-page", 0, &*option_no_empty_page*, 1},
        {"empty-page", 0, &*option_no_empty_page*, 0},
        {"hyphenate-first-word", 0, &*option_hyphen_first*, 1},
        {"no-hyphenate-first-word", 0, &*option_hyphen_first*, 0},
        {"resolution", 1, 0, 0},
        {"mfmode", 1, 0, 0},
#ifdef DEBUG
        {"hint-debug", 1, 0, 0},
        {"hint-debug-help", 0, 0, 0},
#endif
        {0, 0, 0, 0}
    };

1853.   Parsing the command line options is accomplished with the *parse_options* function which in turn uses the *getopt_long_only* function from the C library. This function returns 0 and sets the *option_index* parameter to the option found, or it returns −1 if the end of all options is reached.

⟨ TeX Live functions 1847 ⟩ +≡
  static void *parse_options*(**int** *argc*, **char** *∗argv*[ ])
  { **loop** {
     int *option_index*;
     int *g* ← *getopt_long_only*(*argc*, *argv*, "+", *long_options*, &*option_index*);
     if (*g* ≡ 0) {
      ⟨ handle the options 1857 ⟩ }
     else if (*g* ≡ '?') {
      fprintf(*stderr*, "Try␣'%s␣--help'␣for␣more␣information\n", *argv*[0]); *exit*(1);
     }
     else if (*g* ≡ −1) **break**;
   }
   ⟨ Check the environment for extra settings 1863 ⟩
  }

1854.   ⟨ Forward declarations 52 ⟩ +≡
  static void *parse_options*(**int** *argc*, **char** *∗argv*[ ]);

1855.   Before we can call the *parse_options* function, we might need some special preparations for Windows.

⟨ parse options 1855 ⟩ ≡
#if defined (WIN32)
  { **char** *∗enc*;
    kpse_set_program_name(*argv*[0], Λ); *enc* ← *kpse_var_value*("command_line_encoding");
    get_command_line_args_utf8(*enc*, &*argc*, &*argv*);
    parse_options(*argc*, *argv*); ⟨ record texmf.cnf 1872 ⟩
  }
#else
  parse_options(*ac*, *av*);
#endif
This code is used in section 1847.

1856.   To handle the options, we compare the name at the given *option_index* with the different option names. This is not a very efficient method, but the impact is low and it's simple to write.

    Comparing the name of the argument with the *name* field in the *option* structure is done in the auxiliary function *argument_is*. Unfortunately the *name* field is in conflict with the *name* macro defined by TeX. To avoid the conflict, the *argument_is* function goes just after the kpathsea.h header file that defines the option structure.

⟨ Header files and function declarations 9 ⟩ +≡
#include <kpathsea/kpathsea.h>
  static int *argument_is*(**struct** *option* *∗opt*, **char** *∗s*)
  { **return** STREQ(*opt* → *name*, *s*); }
#define ARGUMENT_IS(*S*) *argument_is*(*long_options* + *option_index*, *S*)

1857.   Now we can handle the first two options:

⟨ handle the options 1857 ⟩ ≡
  if (ARGUMENT_IS("help")) *usage_help* ( );
  else if (ARGUMENT_IS("version")) { *printf* (*banner* "\n"
    "HINT␣version␣" HINT_VERSION_STRING "\n"
    "Prote␣version␣" *Prote_version_string* "\n"); *exit*(0); }

See also sections 1858, 1859, 1860, 1861, 1874, and 1877.

This code is used in section 1853.

1858.   The "interaction" option sets the *interaction_option* variable based on its string argument contained
in the *optarg* variable. If defined, the *interaction_option* will be used to set TeX's *interaction* variable in
the *initialize* and the *undump* functions.

⟨ handle the options 1857 ⟩ +≡
  else if (ARGUMENT_IS("interaction")) {
    if (STREQ(*optarg*, "batchmode")) *interaction_option* ← *batch_mode*;
    else if (STREQ(*optarg*, "nonstopmode")) *interaction_option* ← *nonstop_mode*;
    else if (STREQ(*optarg*, "scrollmode")) *interaction_option* ← *scroll_mode*;
    else if (STREQ(*optarg*, "errorstopmode")) *interaction_option* ← *error_stop_mode*;
    else WARNING1("Ignoring␣unknown␣argument␣'%s'␣to␣--interaction", *optarg*);
  }

1859.   The next two options pass the string argument to the kpathsearch library.

⟨ handle the options 1857 ⟩ +≡
  else if (ARGUMENT_IS("mktex")) *kpse_maketex_option* (*optarg*, *true*);
  else if (ARGUMENT_IS("no-mktex")) *kpse_maketex_option* (*optarg*, *false*);

1860.   To debug the searching done by the kpathsearch library, the following option can be used. The
argument value 3 is a good choice to start with.

⟨ handle the options 1857 ⟩ +≡
  else if (ARGUMENT_IS("kpathsea-debug")) *kpathsea_debug* |= *atoi*(*optarg*);

1861.   The next set of options take a string argument and assign it to the corresponding string variable.

⟨ handle the options 1857 ⟩ +≡
  else if (ARGUMENT_IS("progname")) *user_progname* ← *normalize_quotes* (*optarg*, "program␣name");
  else if (ARGUMENT_IS("fmt")) *dump_name* ← *normalize_quotes* (*optarg*, "format␣name");
  else if (ARGUMENT_IS("output-directory"))
    output_directory ← *normalize_quotes* (*optarg*, "output␣directory");
  else if (ARGUMENT_IS("jobname")) *c_job_name* ← *normalize_quotes* (*optarg*, "job␣name");

1862. When string arguments specify files or directories, special care is needed if arguments are quoted and/or contain spaces. The function *normalize_quotes* makes sure that arguments containing spaces get quotes around them and it checks for unbalanced quotes.

⟨ TeX Live auxiliary functions 1849 ⟩ +≡

```
static char *normalize_quotes(const char *nom, const char *mesg)
{ int quoted ← false;
  int must_quote ← (strchr(nom, '␣') ≠ Λ);
  char *ret ← xmalloc(strlen(nom) + 3);    ▷ room for two quotes and NUL ◁
  char *p ← ret;
  const char *q;
  if (must_quote) *p++ ← '"';
  for (q ← nom; *q; q++)
    if (*q ≡ '"') quoted ← ¬quoted; else *p++ ← *q;
  if (must_quote) *p++ ← '"';
  *p ← '\0';
  if (quoted) {
    fprintf(stderr, "!␣Unbalanced␣quotes␣in␣%s␣%s\n", mesg, nom); exit(1);
  }
  return ret;
}
```

1863. If the output directory was specified on the command line, we save it in an environment variable so that subbrocesses can get the value. If on the other hand the environment specifies a directory and the command line does not, save the value from the environment to the global variable so that it is used in the rest of the code.

⟨ Check the environment for extra settings 1863 ⟩ ≡

```
if (output_directory) xputenv("TEXMF_OUTPUT_DIRECTORY", output_directory);
else if (getenv("TEXMF_OUTPUT_DIRECTORY")) output_directory ← getenv("TEXMF_OUTPUT_DIRECTORY");
```

This code is used in section 1853.

1864. Passing a file name as a general text argument.

scan_file_name uses the following code to parse a file name given as a general text argument. Such an argument can be any token list starting with a left brace and ending with a right brace. This token list is then expanded (without the leading and trailing braces) and printed into the string pool without making it yet an official string. After removing all double quotes, because this is current practice for TEX engines that are part of TEX Live, and setting the area and extension delimiters, all temporary garbage used so far is freed.

Due to the expansion of the token list, this code and hence the *scan_file_name* procedure is recursive. One can provide the name of a file as the content of an other file.

$\langle$ Define a general text file name and **goto** *done* 1864 $\rangle \equiv$
    { *back_input*( ); *name_in_progress* ← *false*;   ▷ this version is recursive... ◁
        cur_cs ← *input_loc*;   ▷ *scan_toks* will set *warning_index* from it ◁
        scan_general_x_text( ); *old_setting* ← *selector*; *selector* ← *new_string*; *token_show*(*link*(*garbage*));
        selector ← *old_setting*; $\langle$ Suppress double quotes in braced input file name 1865 $\rangle$
        j ← *pool_ptr* − 1;
        while (($j \geq$ *str_start*[*str_ptr*]) ∧ (*area_delimiter* ≡ 0)) { **if** ((*str_pool*[*j*] ≡ '/'))
            area_delimiter ← *j* − *str_start*[*str_ptr*];
          if ((*ext_delimiter* ≡ 0) ∧ (*str_pool*[*j*] ≡ '.')) *ext_delimiter* ← *j* − *str_start*[*str_ptr*];
          decr(*j*);
        }
        flush_list(*link*(*garbage*)); **goto** *done*;
    }
This code is used in section 526.

1865.   A simple loop removes the double quotes and adjusts the *pool_ptr*.

$\langle$ Suppress double quotes in braced input file name 1865 $\rangle \equiv$
    for (*k* ← *j* ← *str_start*[*str_ptr*]; *k* < *pool_ptr*; *k*++) { **if** (*str_pool*[*k*] ≠ '"') {
        str_pool[*j*] ← *str_pool*[*k*]; *incr*(*j*);
      }
    }
    pool_ptr ← *j*;
This code is used in section 1864.

1866.   The -recorder Option.   The recorder option can be used to enable the file name recorder. It is crucial for getting a reliable list of files used in a given run. Many post-processors use it, and it is used in TeX Live for checking the format building infrastructure.

When we start the file name recorder, we would like to use mkstemp, but it is not portable, and doing the autoconfiscation (and providing fallbacks) is more than we want to cope with. So we have to be content with using a default name. We throw in the pid so at least parallel builds might work. Windows, however, seems to have no *pid_t*, so instead of storing the value returned by *getpid*, we immediately consume it.

⟨ TeX Live auxiliary functions 1849 ⟩ +≡
  static char *∗recorder_name* ← Λ;
  static FILE *∗recorder_file* ← Λ;

  static void *recorder_start*(**void**)
  {
    char *∗cwd*;
    char *pid_str*[MAX_INT_LENGTH];

    sprintf(*pid_str*, "%ld", (**long**) *getpid*());
    recorder_name ← *concat3*(*kpse_program_name*, *pid_str*, ".fls");
    if (*output_directory*) {
      char *∗temp* ← *concat3*(*output_directory*, DIR_SEP_STRING, *recorder_name*);

      free(*recorder_name*); *recorder_name* ← *temp*;
    }
    recorder_file ← *xfopen*(*recorder_name*, FOPEN_W_MODE); *cwd* ← *xgetcwd*();
    fprintf(*recorder_file*, "PWD␣%s\n", *cwd*); *free*(*cwd*);
  }

1867.   After we know the log file name, we have used *recorder_change_filename* to change the name of the recorder file to the usual thing.

⟨ Forward declarations 52 ⟩ +≡
  static void *recorder_change_filename*(**const char** *∗new_name*);

1868.   Now its time to define this function. Unfortunately, we have to explicitly take the output directory into account, since the new name we are called with does not; it is just the log file name with .log replaced by .fls.

1869.   ⟨T$_E$X Live auxiliary functions 1849⟩ +≡
  static void *recorder_change_filename*(**const char** *∗new_name*)
  {
     char *∗temp* ← Λ;

     if (¬*recorder_file*) **return**;
#**if defined** (_WIN32)
     fclose(*recorder_file*);   ▷ An open file cannot be renamed. ◁
#**endif**   ▷ _WIN32 ◁
     if (*output_directory*) {
        temp ← *concat3*(*output_directory*, DIR_SEP_STRING, *new_name*); *new_name* ← *temp*;
     }
#**if defined** (_WIN32)
     remove(*new_name*);   ▷ A file with the *new_name* must not exist. ◁
#**endif**   ▷ _WIN32 ◁
     rename(*recorder_name*, *new_name*); *free*(*recorder_name*); *recorder_name* ← *xstrdup*(*new_name*);
#**if defined** (_WIN32)
     recorder_file ← *xfopen*(*recorder_name*, FOPEN_A_MODE);   ▷ A closed file must be opened. ◁
#**endif**   ▷ _WIN32 ◁
     if (*temp*) *free*(*temp*);
  }

1870.   Now we are ready to record file names. The prefix INPUT is added to an input file and the prefix
OUTPUT to an output file. But both functions for recording a file name use the same function otherwise,
which on first use will start the recorder.

⟨T$_E$X Live auxiliary functions 1849⟩ +≡
  static void *recorder_record_name*(**const char** *∗pfx*, **const char** *∗fname*)
  { **if** (*recorder_enabled*) {
        if (¬*recorder_file*) *recorder_start*( );
        fprintf(*recorder_file*, "%s␣%s\n", *pfx*, *fname*); *fflush*(*recorder_file*);
     }
  }
  static void *recorder_record_input*(**const char** *∗fname*)
  {
     recorder_record_name("INPUT", *fname*);
  }
  static void *recorder_record_output*(**const char** *∗fname*)
  {
     recorder_record_name("OUTPUT", *fname*);
  }

1871.   Because input files are also recorded when writing the optional sections, we need the following
declaration.
⟨Forward declarations 52⟩ +≡
  static void *recorder_record_input*(**const char** *∗fname*);

1872.   In WIN32, texmf.cnf is not recorded in the case of `-recorder`, because *parse_options* is executed after the start of kpathsea due to special initializations. Therefore we record `texmf.cnf` with the following code:

⟨ record `texmf.cnf` 1872 ⟩ ≡
  if (*recorder_enabled*) {
    char ∗∗*p* ← *kpse_find_file_generic*(`"texmf.cnf"`, *kpse_cnf_format*, 0, 1);
    if (*p* ∧ ∗*p*) {
      char ∗∗*pp* ← *p*;
      while (∗*p*) {
        recorder_record_input(∗*p*); *free*(∗*p*); *p*++;
      }
      free(*pp*);
    }
  }

This code is used in section 1855.

1873.   The -cnf-line Option.   With the -cnf-line option it is possible to specify a line of text as if this line were part of TEX's configuration file—even taking precedence over conflicting lines in the configuration file. For example it is possible to change TEX's TEXINPUTS variable by saying --cnf-line=TEXINPUTS=/foo. The configuration lines are temporarily stored in the variable *cnf_lines* and counted in *cnf_count* because we can send them to the kpathsearch library only after the library has been initialized sufficiently.

⟨ Global variables 13 ⟩ +≡
  static char ∗∗*cnf_lines* ← Λ;
  static int *cnf_count* ← 0;

**1874.   ** ⟨ handle the options 1857 ⟩ +≡
  else if (ARGUMENT_IS("cnf-line")) *add_cnf_line*(*optarg*);

1875.   The function *add_cnf_line* stores the given command line argument in the variable *cnf_lines*.

⟨ TEX Live auxiliary functions 1849 ⟩ +≡
  static void *add_cnf_line*(**char** ∗*arg*)
  { *cnf_count* ++; *cnf_lines* ← *xrealloc*(*cnf_lines*, *sizeof*(**char** ∗) ∗ *cnf_count*);
    cnf_lines[*cnf_count* − 1] ← *arg*;
  }

1876.   To activate the configuration lines they are passed to the kpathsearch library.

⟨ activate configuration lines 1876 ⟩ ≡
#if 1   ▷ this function does not exists always ◁
  { **int** *i*;
    for (*i* ← 0; *i* < *cnf_count*; *i*++) *kpathsea_cnf_line_env_progname*(*kpse_def*, *cnf_lines*[*i*]);
    free(*cnf_lines*);
  }
#endif
This code is used in section 1847.

1877.   HiT_EX specific command line options.   HiT_EX provides options to set the METAFONT mode and the resolution if `.pk` fonts must be rendered and/or included in the `.hnt` output file. Further, a lot of debug output can be generated if HiT_EX was compiled with debugging enabled. The `-hint-debug-help` option gives a short summary of what to expect.

⟨ handle the options 1857 ⟩ +≡

```
  else if (ARGUMENT_IS("resolution")) {
    option_dpi_str ← optarg;  option_dpi ← strtol(option_dpi_str, Λ, 10);
  }
  else if (ARGUMENT_IS("mfmode")) option_mfmode ← optarg;
#ifdef DEBUG
  else if (ARGUMENT_IS("hint-debug")) debugflags ← strtol(optarg, Λ, 16);
  else if (ARGUMENT_IS("hint-debug-help")) {
    fprintf(stderr,
    "To␣generate␣HINT␣format␣debug␣output␣use␣the␣option\n""␣-hint-debug=XX"
        "\t\t␣XX␣is␣a␣hexadecimal␣value.␣OR␣together␣these␣values:\n");
    fprintf(stderr, "\t␣XX=%04X␣\t␣basic␣debugging\n", DBGBASIC);
    fprintf(stderr, "\t␣XX=%04X␣\t␣tag␣debugging\n", DBGTAGS);
    fprintf(stderr, "\t␣XX=%04X␣\t␣node␣debugging\n", DBGNODE);
    fprintf(stderr, "\t␣XX=%04X␣\t␣definition␣debugging\n", DBGDEF);
    fprintf(stderr, "\t␣XX=%04X␣\t␣directory␣debugging\n", DBGDIR);
    fprintf(stderr, "\t␣XX=%04X␣\t␣range␣debugging\n", DBGRANGE);
    fprintf(stderr, "\t␣XX=%04X␣\t␣float␣debugging\n", DBGFLOAT);
    fprintf(stderr, "\t␣XX=%04X␣\t␣compression␣debugging\n", DBGCOMPRESS);

    fprintf(stderr, "\t␣XX=%04X␣\t␣TeX␣debugging\n", DBGTEX);
    fprintf(stderr, "\t␣XX=%04X␣\t␣page␣debugging\n", DBGPAGE);
    fprintf(stderr, "\t␣XX=%04X␣\t␣font␣debugging\n", DBGFONT);
    exit(0);
  }
#endif
```

1878.   The Input File.   After we are done with the options, we inform the `kpathsearch` library about the program name. This is an important piece of information for the library because the library serves quite different programs and its behavior can be customized for each program using configuration files. After the program and engine name is set, the library is ready to use.

⟨ set the program and engine name 1878 ⟩ ≡
   if (¬*user_progname*) *user_progname* ← *dump_name*;
#if defined (WIN32)
   if (*user_progname*) *kpse_reset_program_name*(*user_progname*);
#else
  kpse_set_program_name(*argv*[0], *user_progname*);
#endif
  xputenv("engine", "hitex");

This code is used in section 1847.

1879.   After the options, the command line usually continues with the name of the input file. Getting a hold of the input file name can be quite complicated, but the `kpathsearch` library will help us to do the job.

   We start by looking at the first argument after the options: If it does not start with an "`&`" and neither with a "`\`", it's a simple file name. Under Windows, however, filenames might start with a drive letter followed by a colon and a "`\`" which is used to separate directory names. Finally, if the filename is a quoted string, we need to remove the quotes before we use the `kpathsearch` library to find it and reattach the quotes afterward.

⟨ TEX Live auxiliary functions 1849 ⟩ +≡
#ifdef WIN32
  static void *clean_windows_filename*(**char** *filename*)
  { **if** (*strlen*(*filename*) > 2 ∧ *isalpha*(*filename*[0]) ∧ *filename*[1] ≡ '`:`' ∧ *filename*[2] ≡ '`\\`') {
    char *∗pp*;
    for (*pp* ← *filename*; *∗pp*; *pp*++)
      if (*∗pp* ≡ '`\\`') *∗pp* ← '`/`';
    }
  }
#endif
  static char *∗find_file*(**char** *∗fname*, **kpse_file_format_type** *t*, **int** *mx*)
  { **char** *∗filename*;
    int *final_quote* ← (**int**) *strlen*(*fname*) − 1;
    int *quoted* ← *final_quote* > 1 ∧ *fname*[0] ≡ '`"`' ∧ *fname*[*final_quote*] ≡ '`"`';
    if (*quoted*) {   ▷ Overwrite last quote and skip first quote. ◁
      fname[*final_quote*] ← '`\0`'; *fname*++;
    }
    filename ← *kpse_find_file*(*fname*, *t*, *mx*);
    if (*full_name_of_file* ≠ Λ) {
      free(*full_name_of_file*); *full_name_of_file* ← Λ;
    }
    if (*filename* ≠ Λ) *full_name_of_file* ← *strdup*(*filename*);
    if (*quoted*) {   ▷ Undo modifications ◁
      fname−−; *fname*[*final_quote*] ← '`"`';
    }
    return *filename*;
  }
  static char *∗get_input_file_name*(**void**)
  { **char** *∗input_file_name* ← Λ;
    if (*argv*[*optind*] ∧ *argv*[*optind*][0] ≠ '`&`' ∧ *argv*[*optind*][0] ≠ '`\\`') {
#ifdef WIN32
      clean_windows_filename(*argv*[*optind*]);
#endif
      argv[*optind*] ← *normalize_quotes*(*argv*[*optind*], "`input`␣`file`");
      input_file_name ← *find_file*(*argv*[*optind*], *kpse_tex_format*, *false*);
    }
    return *input_file_name*;
  }

1880. After we called $get\_input\_file\_name$, we might need to look at $argv[argc - 1]$ in case we run under Windows.

⟨ set the input file name 1880 ⟩ ≡
  $main\_input\_file \leftarrow get\_input\_file\_name(\,)$;
#ifdef WIN32 ▷ Were we given a simple filename? ◁
  if ($main\_input\_file \equiv \Lambda$) {
    char $*file\_name \leftarrow argv[argc - 1]$;
    if ($file\_name \wedge file\_name[0] \neq$ '−' $\wedge file\_name[0] \neq$ '&' $\wedge file\_name[0] \neq$ '\\') {
      $clean\_windows\_filename(file\_name)$; $file_name \leftarrow normalize_quotes(file_name, $"argument"$)$;
      $main\_input\_file \leftarrow find\_file(file\_name, kpse\_tex\_format, false)$; $argv[argc - 1] \leftarrow file\_name$;
    }
  }
#endif
This code is used in section 1847.

1881. After we have an input file, we make an attempt at filling in options from the `texmf.cfg` file.

⟨ set defaults from the `texmf.cfg` file 1881 ⟩ ≡
  if ($filelineerrorstylep < 0$) $filelineerrorstylep \leftarrow texmf\_yesno($"file_line_error_style"$)$;
  if ($parsefirstlinep < 0$) $parsefirstlinep \leftarrow texmf\_yesno($"parse_first_line"$)$;

This code is used in section 1847.

1882. We needed:

⟨ TEX Live auxiliary functions 1849 ⟩ +≡
  static int $texmf\_yesno($**const char** $*var)$
  { **char** $*value \leftarrow kpse\_var\_value(var)$;
    return $value \wedge (*value \equiv$ 't' $\vee *value \equiv$ 'y' $\vee *value \equiv$ '1'$)$;
  }

1883. We need a stack, matching the $line\_stack$ that contains the source file names. For the full source filenames we use poiters to **char** because these names are just used for output.

⟨ Global variables 13 ⟩ +≡
  static char $*source\_filename\_stack0[max\_in\_open] \leftarrow \{\Lambda\}$,
      $**$**const** $source\_filename\_stack \leftarrow source\_filename\_stack0 - 1$;
  static char $*full\_source\_filename\_stack0[max\_in\_open] \leftarrow \{\Lambda\}$,
      $**$**const** $full\_source\_filename\_stack \leftarrow full\_source\_filename\_stack0 - 1$;
  static char $*full\_name\_of\_file \leftarrow \Lambda$;

1884. The function $print\_file\_line$ prints "file:line:error" style messages using the $source\_filename\_stack$. If it fails to find the file name, it falls back to the "non-file:line:error" style.

⟨ Basic printing procedures 56 ⟩ +≡
  static void $print\_file\_line($**void**$)$
  { **int** $level \leftarrow in\_open$;
    while ($level > 0 \wedge full\_source\_filename\_stack[level] \equiv \Lambda$) $level$−−;
    if ($level \equiv 0$) $print\_nl($"!␣"$)$;
    else {
      $print\_nl($""$)$; $print(full\_source\_filename\_stack[level])$; $print\_char($':'$)$;
      if ($level \equiv in\_open$) $print\_int(line)$;
      else $print\_int(line\_stack[level])$;
      $print($":␣"$)$;
    }
  }

1885. The Format File.   Most of the time TeX is not running as `initex` or `virtex`, but it runs with a format file preloaded. To set the format name, we first check if the format name was given on the command line with an "`&`" prefix, second we might check the first line of the input file, and last, we check if the program is an initex or virtex program.

If we still don't have a format, we use a plain format if running as a virtex, otherwise the program name is our best guess. There is no need to check for an extension, because the `kpathsearch` library will take care of that. We store the format file name in *dump_name* which is used in the function *w_open_in* below.

⟨ set the format name 1885 ⟩ ≡
  if (*parsefirstlinep* ∧ ¬*dump_name*) *parse_first_line*(*main_input_file*);
  if (¬*main_input_file* ∧ *argv*[1] ∧ *argv*[1][0] ≡ '`&`') *dump_name* ← *argv*[1] + 1;
  if (*strcmp*(*kpse_program_name*, "`hinitex`") ≡ 0) *iniversion* ← *true*;
  else if (*strcmp*(*kpse_program_name*, "`hvirtex`") ≡ 0 ∧ ¬*dump_name*) *dump_name* ← "`hitex`";
  if (¬*dump_name*) *dump_name* ← *kpse_program_name*;
  if (¬*dump_name*) {
    fprintf(*stderr*, "`Unable␣to␣determine␣format␣name\n`"); *exit*(1);
  }
  if (*ltxp*) *etexp* ← 1;
  if (*etexp* ∧ ¬*iniversion*) {
    fprintf(*stderr*, "`-etex␣and␣-ltx␣require␣-ini\n`"); *exit*(1);
  }
This code is used in section 1847.

1886.   Here is the function *parse_first_line*. It searches the first line of the file for a TeX comment of the form "%&format"[1]. If found, we will use the format given there.

⟨ TeX Live auxiliary functions 1849 ⟩ +≡
  static void *parse_first_line*(**char** *∗filename*)
  { **FILE** *∗f* ← Λ;

    if (*filename* ≡ Λ) **return**;
    f ← *open_in*(*filename*, *kpse_tex_format*, "r");
    if (*f* ≠ Λ) {
      char *∗r*, *∗s*, *∗t* ← *read_line*(*f*);

      xfclose(*f*, *filename*);
      if (*t* ≡ Λ) **return**;
      s ← *t*;
      if (*s*[0] ≡ '%' ∧ *s*[1] ≡ '&') {
        s ← *s* + 2;
        while (ISBLANK(*∗s*)) ++*s*;
        r ← *s*;
        while (*∗s* ≠ 0 ∧ *∗s* ≠ '␣' ∧ *∗s* ≠ '\r' ∧ *∗s* ≠ '\n') *s*++;
        ∗s ← 0;
        if (*dump_name* ≡ Λ) {
          char *∗f_name* ← *concat*(*r*, ".fmt");
          char *∗d_name* ← *kpse_find_file*(*f_name*, *kpse_fmt_format*, *false*);

          if (*d_name* ∧ *kpse_readable_file*(*d_name*)) {
            dump_name ← *xstrdup*(*r*); *kpse_reset_program_name*(*dump_name*);
          }
          free(*f_name*);
        }
      }
      free(*t*);
    }
  }

---

[1] The idea of using this format came from Wlodzimierz Bzyl.

1887. Commands.   In the old days, TEX was a Pascal program, and standard Pascal did say nothing about a command line. So TEX would open the terminal file for input and read all the information from the terminal. If you don't give TEX command line arguments, this is still true today. In our present time, people got so much used to control the behavior of a program using command line arguments—especially when writing scripts—that TEX Live allows the specification of commands on the command line which TEX would normally expect on the first line of its terminal input.

So our next task is writing a function to add the remainder of the command line to TEX's input buffer. The main job is done by the *input_add_str* function which duplicates part of the *input_ln* function. Further it skips initial spaces and replaces trailing spaces and line endings by a single space.

⟨ TEX Live auxiliary functions 1849 ⟩ +≡
  static void *input_add_char*(**unsigned int** *c*)
  { **if** (*last* ≥ *max_buf_stack*) { *max_buf_stack* ← *last* + 1;
     if (*max_buf_stack* ≡ *buf_size*) ⟨ Report overflow of the input buffer, and abort 35 ⟩;
    }
    buffer[*last*] ← *xord*[*c*]; *incr*(*last*);
  }

  static void *input_add_str*(**const char** *∗str*)
  { **int** *prev_last*;

    while (*∗str* ≡ ' ') *str*++;
    prev_last ← *last*;
    while (*∗str* ≠ 0) *input_add_char*(*∗str*++);
    for (−−*last*; *last* ≥ *first*; −−*last*) {
     char *c* ← *buffer*[*last*];
     if ((*c*) ≠ ' ' ∧ (*c*) ≠ '\r' ∧ (*c*) ≠ '\n') **break**;
    }
    last++;
    if (*last* > *prev_last*) *input_add_char*(' ');
  }

  static int *input_command_line*(**void**)
  { *last* ← *first*;
    while (*optind* < *argc*) *input_add_str*(*argv*[*optind*++]);
    loc ← *first*; **return** (*loc* < *last*);
  }

1888.   ⟨ Forward declarations 52 ⟩ +≡
  static int *input_command_line*(**void**);

1889.   Opening Files.   When we open an output file, there is usually no searching necessary. In the best case, we have an absolute path and can open it. If the path is relative, we try in this order: the *file_name* prefixed by the *output_directory*, the *file_name* as is, and the *file_name* prefixed with the environment variable TEXMFOUTPUT.

If we were successful with one of the modified names, we update *name_of_file*.

⟨ TeX Live functions 1847 ⟩ +≡
```
  static FILE *open_out(const char *file_name, const char *file_mode)
  { FILE *f ← Λ;
    char *new_name ← Λ;
    int absolute ← kpse_absolute_p(file_name, false);
    if (absolute) {
       f ← fopen(file_name, file_mode);
       if (f ≠ Λ) recorder_record_output(file_name);
       return f;
    }
    if (output_directory) {
       new_name ← concat3(output_directory, DIR_SEP_STRING, file_name);
       f ← fopen(new_name, file_mode);

#endif
```

1890.   Format file names must be scanned before TEX's string mechanism has been initialized. The function *update_name_of_file* will set *name_of_file* from a C string.

We dare not give error messages here, since TEX calls this routine before the *error* routine is ready to roll. Instead, we simply drop excess characters, since the error will be detected in another way when a strange file name isn't found.

⟨ TEX Live auxiliary functions 1849 ⟩ +≡
 static void *update_name_of_file*(**const char** *∗s*, **int** *k*)
 { **int** *j*;
  if (*k* ≤ *file_name_size*) *name_length* ← *k*; **else** *name_length* ← *file_name_size*;
  for (*j* ← 0; *j* < *name_length*; *j*++) *name_of_file*[*j* + 1] ← *xchr*[(**int**) *s*[*j*]];
  name_of_file[*name_length* + 1] ← 0;
 }

1891.   In standard TEX, the *reset* macro is used to open input files. The **kpathsearch** library uses different search paths for different types of files and therefore different functions are needed to open these files. The common code is in the function *open_in*.

⟨ TEX Live auxiliary functions 1849 ⟩ +≡
 static FILE *∗open_in*(**char** *∗filename*, **kpse_file_format_type** *t*, **const char** *∗rwb*)
 { **char** *∗fname* ← Λ;
  FILE *∗f* ← Λ;
  fname ← *find_file*(*filename*, *t*, *true*);
  if (*fname* ≠ Λ) { *f* ← *fopen*(*fname*, *rwb*);
   if (*f* ≠ Λ) *recorder_record_input*(*fname*);
   if (*full_name_of_file* ≠ Λ) *free*(*full_name_of_file*);
   full_name_of_file ← *fname*; }
  return *f*;
 }
 static bool *a_open_in*(**alpha_file** *∗f*) ▷ open a text file for input ◁
 { *f*→*f* ← *open_in*((**char** *∗*) *name_of_file* + 1, *kpse_tex_format*, "r");
  if (*f*→*f* ≠ Λ) *get*(*∗f*);
  return *f*→*f* ≠ Λ ∧ *ferror*(*f*→*f*) ≡ 0;
 }
 static bool *b_open_in*(**byte_file** *∗f*) ▷ open a binary file for input ◁
 { *f*→*f* ← *open_in*((**char** *∗*) *name_of_file* + 1, *kpse_tfm_format*, "rb");
  if (*f*→*f* ≠ Λ) *get*(*∗f*);
  return *f*→*f* ≠ Λ ∧ *ferror*(*f*→*f*) ≡ 0;
 }
 static bool *w_open_in*(**word_file** *∗f*) ▷ open a word file for input ◁
 { *f*→*f* ← Λ;
  if (*name_of_file*[1] ≠ 0) *f*→*f* ← *open_in*((**char** *∗*) *name_of_file* + 1, *kpse_fmt_format*, "rb");
  if (*f*→*f* ≠ Λ) *get*(*∗f*);
  return *f*→*f* ≠ Λ ∧ *ferror*(*f*→*f*) ≡ 0;
 }

1892. TEX's *open_fmt_file* function will call the following function either with the name of a format file as given with an "&" prefix in the input or with Λ if no such name was specified. The function will try *dump_name* as a last resort before returning Λ.

⟨ TEX Live functions 1847 ⟩ +≡
  static bool *open_fmt_file*(**void**)
  { **int** *j* ← *loc*;
    if (*buffer*[*loc*] ≡ '&') { *incr*(*loc*); *j* ← *loc*; *buffer*[*last*] ← '␣';
      while (*buffer*[*j*] ≠ '␣') *incr*(*j*);
      update_name_of_file((**char** ∗) *buffer* + *loc*, *j* − *loc*);
      if (*w_open_in*(&*fmt_file*)) **goto** *found*;
    }
    update_name_of_file(*dump_name*, (**int**) *strlen*(*dump_name*));
    if (*w_open_in*(&*fmt_file*)) **goto** *found*;
    name_of_file[1] ← 0; *wake_up_terminal*; *wterm_ln*("I␣can't␣find␣a␣format␣file!"); **return** *false*;
  found: *loc* ← *j*; **return** *true*;
  }

1893. The TEX Live infrastructure is able to generate format files, font metric files, and even some tex files, if required.

⟨ enable the generation of input files 1893 ⟩ ≡

This code is used in section 1847.

1894. Date and Time.   We conclude this chapter using `time.h` to provide a function that is used to initialize TEX's date and time information. Because *time* is one of TEX's macros, we add the function *tl_now* before including TEX's macros to wrap the call to the *time* function. It sets the variable *start_time* and returns a pointer to a **tm** structure to be used later in *fix_date_and_time*.

To support reproducible output, the environment variable `SOURCE_DATE_EPOCH` needs to be checked. If it is set, it is an ASCII representation of a UNIX timestamp, defined as the number of seconds, excluding leap seconds, since 01 Jan 1970 00:00:00 UTC. Its value is then used to initialize the *start_time* variable.

The TEX Live conventions further require that setting the `FORCE_SOURCE_DATE` environment variable to 1 will cause also TEX's primitives `\year`, `\month`, `\day`, and `\time` to use this value as the current time. Looking at the TEX Live code also reveals that these primitives use the local time instead of the GMT if this variable is not set to 1.

⟨ Header files and function declarations 9 ⟩ +≡
#include <time.h>
  static time_t *start_time* ← ((**time_t**) −1);

```

1897. Index.   Here is where you can find all uses of each identifier in the program, with underlined entries pointing to where the identifier was defined. If the identifier is only one letter long, however, you get to see only the underlined entries. *All references are to section numbers instead of page numbers.*

   This index also lists error messages and other aspects of the program that you might want to look up some day. For example, the entry for "system dependencies" lists all sections that should receive special attention from people who are installing TeX in a new operating environment. A list of various things that can't happen appears under "this can't happen". Approximately 40 sections are listed under "inner loop"; these account for about 60% of TeX's running time, exclusive of input and output.

⟨ Accumulate the constant until *cur_tok* is not a suitable digit 445 ⟩   Used in section 444.

⟨ Add primitive definition to the ROM array 1585 ⟩   Used in section 264.

⟨ Add the empty string to the string pool 50 ⟩   Used in section 47.

⟨ Add the width of node *s* to *act_width* 871 ⟩   Used in section 869.

⟨ Add the width of node *s* to *break_width* 842 ⟩   Used in section 840.

⟨ Add the width of node *s* to *disc_width* 870 ⟩   Used in section 869.

⟨ Adjust for the magnification ratio 457 ⟩   Used in section 453.

⟨ Adjust for the setting of \globaldefs 1214 ⟩   Used in section 1211.

⟨ Adjust *shift_up* and *shift_down* for the case of a fraction line 746 ⟩   Used in section 743.

⟨ Adjust *shift_up* and *shift_down* for the case of no fraction line 745 ⟩   Used in section 743.

⟨ Advance *cur_p* to the node following the present string of characters 867 ⟩   Used in section 866.

⟨ Advance past a whatsit node in the *line_break* loop 1363 ⟩   Used in section 866.

⟨ Advance past a whatsit node in the pre-hyphenation loop 1364 ⟩   Used in section 896.

⟨ Advance *r*; **goto** *found* if the parameter delimiter has been fully matched, otherwise **goto** *resume* 394 ⟩
       Used in section 392.

⟨ Allocate a new directory entry 1743 ⟩   Used in section 1746.

⟨ Allocate a new *setpage_node p* 1735 ⟩   Used in section 1734.

⟨ Allocate entire node *p* and **goto** *found* 129 ⟩   Used in section 127.

⟨ Allocate font numbers for glyphs in the pre- and post-break lists 1784 ⟩   Used in section 1783.

⟨ Allocate from the top of node *p* and **goto** *found* 128 ⟩   Used in section 127.

⟨ Apologize for inability to do the operation now, unless \unskip follows non-glue 1106 ⟩   Used in section 1105.

⟨ Apologize for not loading the font, **goto** *done* 567 ⟩   Used in section 566.

⟨ Append a ligature and/or kern to the translation; **goto** *resume* if the stack of inserted ligatures is
       nonempty 910 ⟩   Used in section 906.

⟨ Append a new leader node that uses *cur_box* 1078 ⟩   Used in section 1075.

⟨ Append a new letter or a hyphen level 962 ⟩   Used in section 961.

⟨ Append a new letter or hyphen 937 ⟩   Used in section 935.

⟨ Append a normal inter-word space to the current list, then **goto** *big_switch* 1041 ⟩   Used in section 1030.

⟨ Append a penalty node, if a nonzero penalty is appropriate 890 ⟩   Used in section 880.

⟨ Append an insertion to the current page and **goto** *contribute* 1008 ⟩   Used in section 1000.

⟨ Append any *new_hlist* entries for *q*, and any appropriate penalties 767 ⟩   Used in section 760.

⟨ Append box *cur_box* to the current list, shifted by *box_context* 1076 ⟩   Used in section 1075.

⟨ Append character *cur_chr* and the following characters (if any) to the current hlist in the current font;
   goto *reswitch* when a non-character has been fetched 1034 ⟩   Used in section 1030.

⟨ Append characters of *hu* [*j* ..] to *major_tail*, advancing *j* 917 ⟩   Used in section 916.

⟨ Append inter-element spacing based on *r_type* and *t* 766 ⟩   Used in section 760.

⟨ Append tabskip glue and an empty box to list *u*, and update *s* and *t* as the prototype nodes are passed 809 ⟩
       Used in section 808.

⟨ Append the accent with appropriate kerns, then set *p*: ← *q* 1125 ⟩   Used in section 1123.

⟨ Append the current tabskip glue to the preamble list 778 ⟩   Used in section 777.

⟨ Append the display and perhaps also the equation number 1204 ⟩

⟨ Append the glue or equation number following the display 1205 ⟩

⟨ Append the glue or equation number preceding the display 1203 ⟩

⟨ Append the new box to the current vertical list, followed by the list of special nodes taken out of the box
       by the packager 888 ⟩   Used in section 880.

⟨ Append the value *n* to list *p* 938 ⟩   Used in section 937.

⟨ Assign the values *depth_threshold*: ← *show_box_depth* and *breadth_max*: ← *show_box_breadth* 236 ⟩   Used
       in section 198.

⟨ Assignments 1217, 1218, 1221, 1224, 1225, 1226, 1228, 1232, 1234, 1235, 1241, 1242, 1248, 1252, 1253, 1256, 1264 ⟩   Used
       in section 1211.

⟨ Attach list *p* to the current list, and record its length; then finish up and **return** 1120 ⟩   Used in section 1119.

⟨ Attach the limits to *y* and adjust *height*(*v*), *depth*(*v*) to account for their presence 751 ⟩   Used in section 750.

⟨ Back up an outer control sequence so that it can be reread 337 ⟩   Used in section 336.

⟨ Basic printing procedures 56, 57, 58, 59, 60, 62, 63, 64, 65, 262, 263, 518, 699, 1356, 1506, 1884 ⟩   Used in section 4.

⟨ Break the current page at node *p*, put it in box 255, and put the remaining nodes on the contribution list 1017 ⟩   Used in section 1014.

⟨ Break the paragraph at the chosen breakpoints, justify the resulting lines to the correct widths, and append them to the current vertical list 876 ⟩   Used in section 815.

⟨ Calculate the length, *l*, and the shift amount, *s*, of the display lines 1149 ⟩   Used in section 1145.

⟨ Calculate the natural width, *w*, by which 1146 ⟩

⟨ Call the packaging subroutine, setting *just_box* to the justified box 889 ⟩   Used in section 880.

⟨ Call *try_break* if *cur_p* is a legal breakpoint; on the second pass, also try to hyphenate the next word, if *cur_p* is a glue node; then advance *cur_p* to the next node of the paragraph that could possibly be a legal breakpoint 866 ⟩   Used in section 863.

⟨ Carry out a ligature replacement, updating the cursor structure and possibly advancing *j*; **goto** *resume* if the cursor doesn't advance, otherwise **goto** *done* 911 ⟩   Used in section 909.

⟨ Case statement to copy different types and set *words* to the number of initial words not yet copied 206 ⟩   Used in section 205.

⟨ Cases for 'Fetch the *dead_cycles* or the *insert_penalties*' 1426 ⟩   Used in section 419.

⟨ Cases for *input* 1433 ⟩   Used in section 378.

⟨ Cases for *out_what* 1688 ⟩

⟨ Cases for *print_param* 1391, 1541 ⟩   Used in section 237.

⟨ Cases for *show_whatever* 1409, 1423 ⟩   Used in section 1293.

⟨ Cases of 'Print the result of command *c*' 1560, 1596, 1602, 1614, 1618, 1622, 1626, 1655, 1662, 1669 ⟩   Used in section 472.

⟨ Cases of 'Scan the argument for command *c*' 1559, 1595, 1601, 1613, 1617, 1621, 1625, 1654, 1661, 1668 ⟩   Used in section 471.

⟨ Cases of *assign_toks* for *print_cmd_chr* 1390 ⟩   Used in section 231.

⟨ Cases of *convert* for *print_cmd_chr* 1558, 1594, 1600, 1612, 1616, 1620, 1624, 1653, 1660, 1667 ⟩   Used in section 469.

⟨ Cases of *expandafter* for *print_cmd_chr* 1447, 1581, 1591 ⟩   Used in section 266.

⟨ Cases of *extension* for *print_cmd_chr* 1606, 1681 ⟩   Used in section 1346.

⟨ Cases of *flush_node_list* that arise in mlists only 698 ⟩   Used in section 202.

⟨ Cases of *handle_right_brace* where a *right_brace* triggers a delayed action 1085, 1100, 1118, 1132, 1133, 1168, 1173, 1186 ⟩   Used in section 1068.

⟨ Cases of *if_test* for *print_cmd_chr* 1448, 1574 ⟩   Used in section 488.

⟨ Cases of *input* for *print_cmd_chr* 1432 ⟩   Used in section 377.

⟨ Cases of *last_item* for *print_cmd_chr* 1382, 1396, 1399, 1402, 1405, 1463, 1486, 1490, 1556, 1571, 1605, 1649, 1676, 1691 ⟩   Used in section 417.

⟨ Cases of *left_right* for *print_cmd_chr* 1430 ⟩   Used in section 1189.

⟨ Cases of *main_control* that are for extensions to TEX 1347 ⟩   Used in section 1045.

⟨ Cases of *main_control* that are not part of the inner loop 1045 ⟩   Used in section 1030.

⟨ Cases of *main_control* that build boxes and lists 1056, 1057, 1063, 1067, 1073, 1090, 1092, 1094, 1097, 1102, 1104, 1109, 1112, 1116, 1122, 1126, 1130, 1134, 1137, 1140, 1150, 1154, 1158, 1162, 1164, 1167, 1171, 1175, 1180, 1190, 1193 ⟩   Used in section 1045.

⟨ Cases of *main_control* that don't depend on *mode* 1210, 1268, 1271, 1274, 1276, 1285, 1290 ⟩   Used in section 1045.

⟨ Cases of *prefix* for *print_cmd_chr* 1455 ⟩   Used in section 1209.

⟨ Cases of *print_cmd_chr* for symbolic printing of primitives 227, 231, 239, 249, 266, 335, 377, 385, 412, 417, 469, 488, 492, 781, 984, 1053, 1059, 1072, 1089, 1108, 1115, 1143, 1157, 1170, 1179, 1189, 1209, 1220, 1223, 1231, 1251, 1255, 1261, 1263, 1273, 1278, 1287, 1292, 1295, 1346 ⟩   Used in section 298.

⟨ Cases of *read* for *print_cmd_chr* 1444 ⟩   Used in section 266.

⟨ Cases of **register** for *print_cmd_chr* 1516 ⟩   Used in section 412.

⟨ Cases of *set_page_int* for *print_cmd_chr* 1425 ⟩   Used in section 417.

⟨ Cases of *set_shape* for *print_cmd_chr* 1537 ⟩   Used in section 266.

⟨ Cases of *show_node_list* that arise in mlists only 690 ⟩   Used in section 183.

⟨ Cases of *the* for *print_cmd_chr* 1419 ⟩   Used in section 266.

⟨ Cases of *toks_register* for *print_cmd_chr* 1517 ⟩   Used in section 266.

⟨ Cases of *un_vbox* for *print_cmd_chr* 1534 ⟩   Used in section 1108.

⟨ Cases of *xray* for *print_cmd_chr* 1408, 1417, 1422 ⟩   Used in section 1292.

⟨ Cases where character is ignored 345 ⟩   Used in section 344.

⟨ Change buffered instruction to *y* or *w* and **goto** *found* 613 ⟩   Used in section 612.

⟨ Change buffered instruction to *z* or *x* and **goto** *found* 614 ⟩   Used in section 612.

⟨ Change current mode to −*vmode* for \halign, −*hmode* for \valign 775 ⟩   Used in section 774.

⟨ Change discretionary to compulsory and set *disc_break*: ← *true* 882 ⟩   Used in section 881.

⟨ Change font *dvi_f* to *f* 621 ⟩   Used in section 620.

⟨ Change state if necessary, and **goto switch** if the current character should be ignored, or **goto** *reswitch* if the current character changes to another 344 ⟩   Used in section 343.

⟨ Change the case of the token in *p*, if a change is appropriate 1289 ⟩   Used in section 1288.

⟨ Change the current style and **goto** *delete_q* 763 ⟩   Used in section 761.

⟨ Change the interaction level and **return** 86 ⟩   Used in section 84.

⟨ Change this node to a style node followed by the correct choice, then **goto** *done_with_node* 731 ⟩   Used in section 730.

⟨ Character *k* cannot be printed 49 ⟩   Used in section 48.

⟨ Character *s* is the current new-line character 244 ⟩   Used in sections 58 and 59.

⟨ Check PRoTE "constant" values for consistency 1568 ⟩   Used in section 1380.

⟨ Check flags of unavailable nodes 170 ⟩   Used in section 167.

⟨ Check for charlist cycle 570 ⟩   Used in section 569.

⟨ Check for improper alignment in displayed math 776 ⟩   Used in section 774.

⟨ Check if node *p* is a new champion breakpoint; then **goto** *done* if *p* is a forced break or if the page-so-far is already too full 974 ⟩   Used in section 972.

⟨ Check if node *p* is a new champion breakpoint; then if it is time for a page break, prepare for output, and either fire up the user's output routine and **return** or ship out the page and **goto** *done* 1005 ⟩   Used in section 997.

⟨ Check single-word *avail* list 168 ⟩   Used in section 167.

⟨ Check that another $ follows 1197 ⟩   Used in sections 1194 and 1206.

⟨ Check that the necessary fonts for math symbols are present; if not, flush the current math lists and set *danger*: ← *true* 1195 ⟩   Used in section 1194.

⟨ Check that the nodes following *hb* permit hyphenation and that at least *l_hyf* + *r_hyf* letters have been found, otherwise **goto** *done1* 899 ⟩   Used in section 894.

⟨ Check the "constant" values for consistency 14, 111, 290, 1249 ⟩   Used in section 1332.

⟨ Check the environment for extra settings 1863 ⟩   Used in section 1853.

⟨ Check variable-size *avail* list 169 ⟩   Used in section 167.

⟨ Clean up the memory by removing the break nodes 865 ⟩   Used in sections 815 and 863.

⟨ Clear dimensions to zero 650 ⟩   Used in section 1726.

⟨ Clear off top level from *save_stack* 282 ⟩   Used in section 281.

⟨ Close the format file 1329 ⟩   Used in section 1302.

⟨ Coerce glue to a dimension 451 ⟩   Used in sections 449 and 455.

⟨ Collect output nodes from *∗p* 1721 ⟩   Used in section 1720.

⟨ Complain about an undefined family and set *cur_i* null 723 ⟩   Used in section 722.

⟨ Complain about an undefined macro 370 ⟩   Used in section 367.

⟨ Complain about missing \endcsname 373 ⟩   Used in sections 372 and 1451.

⟨ Complain about unknown unit and **goto** *done2* 459 ⟩   Used in section 458.

⟨ Complain that \the can't do this; give zero result 428 ⟩   Used in section 413.

⟨ Complain that the user should have said \mathaccent 1166 ⟩   Used in section 1165.

⟨ Compleat the incompleat noad 1185 ⟩   Used in section 1184.

⟨ Complete a potentially long \show command 1298 ⟩   Used in section 1293.

⟨ Compute $f = \lfloor 2^{28}(1 + p/q) + \frac{1}{2} \rfloor$ 1642 ⟩   Used in section 1641.

⟨ Compute $p = \lfloor qf/2^{28} + \frac{1}{2} \rfloor - q$ 1645 ⟩   Used in section 1643.

⟨ Compute $f = \lfloor xn/d + \frac{1}{2} \rfloor$ 1484 ⟩   Used in section 1483.

⟨ Compute result of *multiply* or *divide*, put it in *cur_val* 1240 ⟩   Used in section 1236.

⟨ Compute result of **register** or *advance*, put it in *cur_val* 1238 ⟩   Used in section 1236.

⟨ Compute the amount of skew 741 ⟩   Used in section 738.

⟨ Compute the badness, b, of the current page, using *awful_bad* if the box is too full 1007 ⟩   Used in section 1005.

⟨ Compute the badness, b, using *awful_bad* if the box is too full 975 ⟩   Used in section 974.

⟨ Compute the demerits, d, from r to *cur_p* 859 ⟩   Used in section 855.

⟨ Compute the discretionary *break_width* values 840 ⟩   Used in section 837.

⟨ Compute the hash code h 261 ⟩   Used in section 259.

⟨ Compute the mark pointer for mark type t and class *cur_val* 1508 ⟩   Used in section 386.

⟨ Compute the minimum suitable height, w, and the corresponding number of extension steps, n; also set *width*(b) 714 ⟩   Used in section 713.

⟨ Compute the new line width 850 ⟩   Used in section 835.

⟨ Compute the page size 1717 ⟩   Used in section 1748.

⟨ Compute the register location l and its type p; but **return** if invalid 1237 ⟩   Used in section 1236.

⟨ Compute the sum of two glue specs 1239 ⟩   Used in section 1238.

⟨ Compute the sum or difference of two glue specs 1478 ⟩   Used in section 1476.

⟨ Compute the trie op code, v, and set $l: \leftarrow 0$ 965 ⟩   Used in section 963.

⟨ Compute the values of *break_width* 837 ⟩   Used in section 836.

⟨ Consider a node with matching width; **goto** *found* if it's a hit 612 ⟩   Used in section 611.

⟨ Consider the demerits for a line from r to *cur_p*; deactivate node r if it should no longer be active; then **goto** *resume* if a line from r to *cur_p* is infeasible, otherwise record a new feasible break 851 ⟩   Used in section 829.

⟨ Constants in the outer block 11 ⟩   Used in section 4.

⟨ Construct a box with limits above and below it, skewed by *delta* 750 ⟩   Used in section 749.

⟨ Construct a sub/superscript combination box x, with the superscript offset by *delta* 759 ⟩   Used in section 756.

⟨ Construct a subscript box x when there is no superscript 757 ⟩   Used in section 756.

⟨ Construct a superscript box x 758 ⟩   Used in section 756.

⟨ Construct a vlist box for the fraction, according to *shift_up* and *shift_down* 747 ⟩   Used in section 743.

⟨ Construct an extensible character in a new box b, using recipe *rem_byte*(q) and font f 713 ⟩   Used in section 710.

⟨ Contribute an entire group to the current parameter 399 ⟩   Used in section 392.

⟨ Contribute the recently matched tokens to the current parameter, and **goto** *resume* if a partial match is still in effect; but abort if $s \leftarrow null$ 397 ⟩   Used in section 392.

⟨ Convert a final *bin_noad* to an *ord_noad* 729 ⟩   Used in sections 726 and 728.

⟨ Convert *cur_val* to a lower level 429 ⟩   Used in section 413.

⟨ Convert math glue to ordinary glue 732 ⟩   Used in section 730.

⟨ Convert *nucleus*(*q*) to an hlist and attach the sub/superscripts 754 ⟩   Used in section 728.

⟨ Convert string *s* into a new pseudo file 1438 ⟩   Used in section 1437.

⟨ Copy the tabskip glue between columns 795 ⟩   Used in section 791.

⟨ Copy the templates from node *cur_loop* into node *p* 794 ⟩   Used in section 793.

⟨ Copy the token list 466 ⟩   Used in section 465.

⟨ Create a character node *p* for *nucleus*(*q*), possibly followed by a kern node for the italic correction, and set *delta* to the italic correction if a subscript is present 755 ⟩   Used in section 754.

⟨ Create a character node *q* for the next character, but set *q*: ← *null* if problems arise 1124 ⟩   Used in section 1123.

⟨ Create a new array element of type *t* with index *i* 1504 ⟩   Used in section 1503.

⟨ Create a new glue specification whose width is *cur_val*; scan for its stretch and shrink components 462 ⟩   Used in section 461.

⟨ Create a page insertion node with *subtype*(*r*) ← *qi*(*n*), and include the glue correction for box *n* in the current page state 1009 ⟩   Used in section 1008.

⟨ Create an active breakpoint representing the beginning of the paragraph 864 ⟩   Used in section 863.

⟨ Create and append a discretionary node as an alternative to the unhyphenated word, and continue to develop both branches until they become equivalent 914 ⟩   Used in section 913.

⟨ Create equal-width boxes *x* and *z* for the numerator and denominator, and compute the default amounts *shift_up* and *shift_down* by which they are displaced from the baseline 744 ⟩   Used in section 743.

⟨ Create new active nodes for the best feasible breaks just found 836 ⟩   Used in section 835.

⟨ Create the parameter node 1699 ⟩   Used in section 1698.

⟨ Create the *format_ident*, open the format file, and inform the user that dumping has begun 1328 ⟩   Used in section 1302.

⟨ Current *mem* equivalent of glue parameter number *n* 224 ⟩   Used in sections 152 and 154.

⟨ Deactivate node *r* 860 ⟩   Used in section 851.

⟨ Declare PROTE arithmetic routines 1637, 1641, 1643, 1656, 1657, 1658, 1663, 1665 ⟩   Used in section 108.

⟨ Declare PROTE procedures for strings 1566 ⟩   Used in section 46.

⟨ Declare PROTE procedures for token lists 1563, 1565 ⟩   Used in section 473.

⟨ Declare ε-TeX procedures for expanding 1436, 1494, 1499, 1503 ⟩   Used in section 366.

⟨ Declare ε-TeX procedures for scanning 1414, 1456, 1465, 1470 ⟩   Used in section 409.

⟨ Declare ε-TeX procedures for token lists 1415, 1437 ⟩   Used in section 464.

⟨ Declare ε-TeX procedures for tracing and input 284, 1393, 1394, 1440, 1441, 1458, 1460, 1461, 1505, 1507, 1521, 1522, 1523, 1524, 1525 ⟩   Used in section 268.

⟨ Declare ε-TeX procedures for use by *main_control* 1388, 1411, 1427 ⟩   Used in section 815.

⟨ Declare action procedures for use by *main_control* 1043, 1047, 1049, 1050, 1051, 1054, 1060, 1061, 1064, 1069, 1070, 1075, 1079, 1084, 1086, 1091, 1093, 1095, 1096, 1099, 1101, 1103, 1105, 1110, 1113, 1117, 1119, 1123, 1127, 1129, 1131, 1135, 1136, 1138, 1142, 1151, 1155, 1159, 1160, 1163, 1165, 1172, 1174, 1176, 1181, 1191, 1194, 1200, 1211, 1270, 1275, 1279, 1288, 1293, 1302, 1348, 1377 ⟩   Used in section 1030.

⟨ Declare math construction procedures 734, 735, 736, 737, 738, 743, 749, 752, 756, 762 ⟩   Used in section 726.

⟨ Declare procedures for preprocessing hyphenation patterns 944, 948, 949, 953, 957, 959, 960, 966 ⟩   Used in section 942.

⟨ Declare procedures needed for displaying the elements of mlists 691, 692, 694 ⟩   Used in section 179.

⟨ Declare procedures needed for expressions 1466, 1471 ⟩   Used in section 461.

⟨ Declare procedures needed in *do_extension* 1349, 1350, 1351 ⟩   Used in section 1348.

⟨ Declare procedures needed in *hlist_out*, *vlist_out* 1369, 1371, 1374 ⟩   Used in section 619.

⟨ Declare procedures needed in *out_what* 1687 ⟩   Used in section 1374.

⟨ Declare procedures that scan font-related stuff 577, 578 ⟩   Used in section 409.

⟨ Declare procedures that scan restricted classes of integers 433, 434, 435, 436, 437, 1495 ⟩ Used in section 409.

⟨ Declare subprocedures for *line_break* 826, 829, 877, 895, 942 ⟩ Used in section 815.

⟨ Declare subprocedures for *prefixed_command* 1215, 1229, 1236, 1243, 1244, 1245, 1246, 1247, 1257, 1265 ⟩ Used in section 1211.

⟨ Declare subprocedures for *scan_expr* 1477, 1481, 1483 ⟩ Used in section 1466.

⟨ Declare subprocedures for *var_delimiter* 709, 711, 712 ⟩ Used in section 706.

⟨ Declare the function called *do_marks* 1509 ⟩ Used in section 977.

⟨ Declare the function called *fin_mlist* 1184 ⟩ Used in section 1174.

⟨ Declare the function called *open_fmt_file* 524 ⟩ Used in section 1303.

⟨ Declare the function called *reconstitute* 906 ⟩ Used in section 895.

⟨ Declare the procedure called *align_peek* 785 ⟩ Used in section 800.

⟨ Declare the procedure called *fire_up* 1012 ⟩

⟨ Declare the procedure called *get_preamble_token* 782 ⟩ Used in section 774.

⟨ Declare the procedure called *handle_right_brace* 1068 ⟩ Used in section 1030.

⟨ Declare the procedure called *init_span* 787 ⟩ Used in section 786.

⟨ Declare the procedure called *insert_relax* 379 ⟩ Used in section 366.

⟨ Declare the procedure called *macro_call* 389 ⟩ Used in section 366.

⟨ Declare the procedure called *print_cmd_chr* 298 ⟩ Used in section 252.

⟨ Declare the procedure called *print_skip_param* 225 ⟩ Used in section 179.

⟨ Declare the procedure called *runaway* 306 ⟩ Used in section 119.

⟨ Declare the procedure called *show_token_list* 292 ⟩ Used in section 119.

⟨ Decry the invalid character and **goto** *restart* 346 ⟩ Used in section 344.

⟨ Define a general text file name and **goto** *done* 1864 ⟩ Used in section 526.

⟨ Delete $c -$ "0" tokens and **goto** *resume* 88 ⟩ Used in section 84.

⟨ Delete the page-insertion nodes 1019 ⟩ Used in section 1014.

⟨ Destroy the t nodes following q, and make r point to the following node 883 ⟩ Used in section 882.

⟨ Determine horizontal glue shrink setting, then **return** or **goto** *common_ending* 664 ⟩ Used in section 657.

⟨ Determine horizontal glue stretch setting, then **return** or **goto** *common_ending* 658 ⟩ Used in section 657.

⟨ Determine the displacement, d, of the left edge of the equation 1202 ⟩

⟨ Determine the shrink order 665 ⟩ Used in sections 664, 676, and 796.

⟨ Determine the stretch order 659 ⟩ Used in sections 658, 673, and 796.

⟨ Determine the value of $height(r)$ and the appropriate glue setting 672 ⟩

⟨ Determine the value of $width(r)$ and the appropriate glue setting; then **return** or **goto** *common_ending* 657 ⟩ Used in section 1726.

⟨ Determine vertical glue shrink setting, then **return** or **goto** *common_ending* 676 ⟩ Used in section 672.

⟨ Determine vertical glue stretch setting, then **return** or **goto** *common_ending* 673 ⟩ Used in section 672.

⟨ Discard erroneous prefixes and **return** 1212 ⟩ Used in section 1211.

⟨ Discard the prefixes \long and \outer if they are irrelevant 1213 ⟩ Used in section 1211.

⟨ Dispense with trivial cases of void or bad boxes 978 ⟩ Used in section 977.

⟨ Display adjustment p 197 ⟩ Used in section 183.

⟨ Display box p 184 ⟩ Used in section 183.

⟨ Display choice node p 695 ⟩ Used in section 690.

⟨ Display discretionary p 195 ⟩ Used in section 183.

⟨ Display fraction noad p 697 ⟩ Used in section 690.

⟨ Display glue p 189 ⟩ Used in section 183.

⟨ Display insertion p 188 ⟩ Used in section 183.

⟨ Display kern p 191 ⟩ Used in section 183.

⟨ Display leaders p 190 ⟩ Used in section 189.

⟨ Display ligature p 193 ⟩ Used in section 183.

⟨ Display mark p 196 ⟩ Used in section 183.

⟨ Display math node p 192 ⟩ Used in section 183.

⟨ Display node p 183 ⟩ Used in section 182.

⟨ Display normal noad p 696 ⟩   Used in section 690.

⟨ Display penalty p 194 ⟩   Used in section 183.

⟨ Display rule p 187 ⟩   Used in section 183.

⟨ Display special fields of the unset node p 185 ⟩   Used in section 184.

⟨ Display the current context 312 ⟩   Used in section 311.

⟨ Display the insertion split cost 1011 ⟩   Used in section 1010.

⟨ Display the page break cost 1006 ⟩   Used in section 1005.

⟨ Display the token (m, c) 294 ⟩   Used in section 293.

⟨ Display the value of b 502 ⟩   Used in section 498.

⟨ Display the value of $glue\_set(p)$ 186 ⟩   Used in section 184.

⟨ Display the whatsit node p 1357 ⟩   Used in section 183.

⟨ Display token p, and **return** if there are problems 293 ⟩   Used in section 292.

⟨ Do first-pass processing based on $type(q)$; **goto** $done\_with\_noad$ if a noad has been fully processed, **goto**
    $check\_dimensions$ if it has been translated into $new\_hlist(q)$, or **goto** $done\_with\_node$ if a node has
    been fully processed 728 ⟩   Used in section 727.

⟨ Do ligature or kern command, returning to $main\_lig\_loop$ or $main\_loop\_wrapup$ or $main\_loop\_move$ 1040 ⟩
        Used in section 1039.

⟨ Do magic computation 320 ⟩   Used in section 292.

⟨ Do some work that has been queued up for \write 1375 ⟩   Used in section 1374.

⟨ Drop current token and complain that it was unmatched 1066 ⟩   Used in section 1064.

⟨ Dump a couple more things and the closing check word 1326 ⟩   Used in section 1302.

⟨ Dump constants for consistency check 1307 ⟩   Used in section 1302.

⟨ Dump regions 1 to 4 of $eqtb$ 1315 ⟩   Used in section 1313.

⟨ Dump regions 5 and 6 of $eqtb$ 1316 ⟩   Used in section 1313.

⟨ Dump the PRòTE state 1545 ⟩   Used in section 1307.

⟨ Dump the ε-TₑX state 1386, 1442 ⟩   Used in section 1307.

⟨ Dump the array info for internal font number k 1322 ⟩   Used in section 1320.

⟨ Dump the dynamic memory 1311 ⟩   Used in section 1302.

⟨ Dump the font information 1320 ⟩   Used in section 1302.

⟨ Dump the hash table 1318 ⟩   Used in section 1313.

⟨ Dump the hyphenation tables 1324 ⟩   Used in section 1302.

⟨ Dump the string pool 1309 ⟩   Used in section 1302.

⟨ Dump the table of equivalents 1313 ⟩   Used in section 1302.

⟨ Dump the ROM array 1586 ⟩   Used in section 1307.

⟨ Either append the insertion node p after node q, and remove it from the current page, or delete
        $node(p)$ 1022 ⟩   Used in section 1020.

⟨ Either insert the material specified by node p into the appropriate box, or hold it for the next page; also
        delete node p from the current page 1020 ⟩   Used in section 1014.

⟨ Either process \ifcase or set b to the value of a boolean condition 501 ⟩   Used in section 498.

⟨ Empty the last bytes out of dvi_buf 599 ⟩   Used in section 642.

⟨ Enable ε-TₑX and furthermore Prote, if requested 1380 ⟩   Used in section 1337.

⟨ Ensure that box 255 is empty after output 1028 ⟩   Used in section 1026.

⟨ Ensure that box 255 is empty before output 1015 ⟩   Used in section 1014.

⟨ Ensure that $trie\_max \geq h + 256$ 954 ⟩   Used in section 953.

⟨ Enter a hyphenation exception 939 ⟩   Used in section 935.

⟨ Enter all of the patterns into a linked trie, until coming to a right brace 961 ⟩   Used in section 960.

⟨ Enter as many hyphenation exceptions as are listed, until coming to a right brace; then **return** 935 ⟩   Used
        in section 934.

⟨ Enter $skip\_blanks$ state, emit a space 349 ⟩   Used in section 347.

⟨ Error handling procedures 72, 78, 81, 82, 93, 94, 95 ⟩   Used in section 4.

⟨ Evaluate the current expression 1476 ⟩   Used in section 1467.

⟨ Examine node p in the hlist, taking account of its effect 651 ⟩

⟨ Forbidden cases detected in *main_control* 1048, 1098, 1111, 1144 ⟩   Used in section 1045.

⟨ Forward declarations 52, 1562, 1564, 1695, 1716, 1848, 1854, 1867, 1871, 1888 ⟩   Used in section 4.

⟨ Freeze the page specs if called for 1713 ⟩   Used in section 1712.

⟨ Generate a *down* or *right* command for w and **return** 610 ⟩   Used in section 607.

⟨ Generate a *y0* or *z0* command in order to reuse a previous appearance of w 609 ⟩   Used in section 607.

⟨ Generate all PRóTE primitives 1555, 1570, 1573, 1580, 1590, 1593, 1599, 1604, 1611, 1615, 1619, 1623, 1648, 1652, 1659, 1666, 1671, 1675, 1680 ⟩   Used in section 1380.

⟨ Generate all ε-TeX primitives 1381, 1389, 1395, 1398, 1401, 1404, 1407, 1416, 1418, 1421, 1424, 1429, 1431, 1443, 1446, 1454, 1462, 1485, 1489, 1493, 1533, 1536, 1540 ⟩   Used in section 1380.

⟨ Generate the MD5 hash for a file 1627 ⟩

⟨ Generate the MD5 hash for a string 1628 ⟩

⟨ Get ready to compress the trie 952 ⟩   Used in section 966.

⟨ Get ready to start line breaking 816, 827, 834, 848 ⟩   Used in section 815.

⟨ Get the first line of input and prepare to start 1337 ⟩   Used in section 1332.

⟨ Get the next non-blank non-call token 406 ⟩   Used in sections 405, 441, 455, 503, 577, 1045, 1349, 1468, and 1469.

⟨ Get the next non-blank non-relax non-call token 404 ⟩   Used in sections 403, 526, 1078, 1084, 1151, 1160, 1211, 1226, and 1270.

⟨ Get the next non-blank non-sign token; set *negative* appropriately 441 ⟩   Used in sections 440, 448, and 461.

⟨ Get the next token, suppressing expansion 358 ⟩   Used in section 357.

⟨ Get user's advice and **return** 83 ⟩   Used in section 82.

⟨ Give diagnostic information, if requested 1031 ⟩   Used in section 1030.

⟨ Give improper \hyphenation error 936 ⟩   Used in section 935.

⟨ Global variables 13, 20, 26, 30, 32, 39, 54, 73, 76, 79, 96, 104, 115, 116, 117, 118, 124, 165, 173, 181, 213, 246, 253, 256, 271, 286, 297, 301, 304, 305, 308, 309, 310, 333, 361, 382, 387, 388, 410, 438, 447, 480, 489, 493, 512, 513, 527, 532, 539, 549, 550, 555, 592, 595, 605, 616, 646, 647, 661, 684, 719, 724, 765, 770, 814, 821, 823, 825, 828, 833, 839, 847, 872, 892, 900, 905, 907, 921, 926, 943, 947, 950, 971, 980, 982, 989, 1032, 1074, 1266, 1281, 1299, 1305, 1331, 1342, 1345, 1384, 1392, 1434, 1457, 1498, 1500, 1519, 1530, 1531, 1539, 1543, 1567, 1582, 1635, 1646, 1647, 1672, 1678, 1846, 1852, 1873, 1883 ⟩   Used in section 4.

⟨ Go into display math mode 1145 ⟩   Used in section 1138.

⟨ Go into ordinary math mode 1139 ⟩   Used in sections 1138 and 1142.

⟨ Go through the preamble list, determining the column widths and changing the alignrecords to dummy unset boxes 801 ⟩   Used in section 800.

⟨ Grow more variable-size memory and **goto** *restart* 126 ⟩   Used in section 125.

⟨ Handle \readline and **goto** *done* 1445 ⟩   Used in section 483.

⟨ Handle \unexpanded or \detokenize and **return** 1420 ⟩   Used in section 465.

⟨ Handle non-positive logarithm 1639 ⟩   Used in section 1637.

⟨ Handle saved items and **goto** *done* 1535 ⟩   Used in section 1110.

⟨ Handle situations involving spaces, braces, changes of state 347 ⟩   Used in section 344.

⟨ Header files and function declarations 9, 1693, 1844, 1856, 1894, 1895 ⟩   Used in section 4.

⟨ HiTeX auxiliary routines 1703, 1704, 1705, 1706, 1707, 1708, 1709, 1710, 1715, 1720, 1737, 1746, 1747, 1748, 1749, 1755, 1761, 1765, 1771, 1772, 1774, 1777, 1778, 1782, 1792, 1793, 1794, 1796, 1807, 1809, 1814, 1816, 1832, 1833 ⟩   Used in section 1694.

⟨ HiTeX function declarations 1836, 1838 ⟩   Used in section 1694.

⟨ HiTeX macros 1744, 1756, 1797 ⟩   Used in section 1694.

⟨ HiTeX routines 1696, 1697, 1698, 1701, 1711, 1712, 1723, 1726, 1728, 1730, 1731, 1732, 1733, 1734, 1736, 1739, 1740, 1750, 1766, 1780, 1783, 1787, 1788, 1803, 1835, 1837, 1841 ⟩   Used in section 1694.

⟨ HiTeX variables 1718, 1729, 1745, 1752, 1753, 1758, 1759, 1763, 1768, 1769, 1775, 1781, 1786, 1790, 1808 ⟩   Used in section 1694.

⟨ If a line number class has ended, create new active nodes for the best feasible breaks in that class; then **return** if r ≡ *last_active*, otherwise compute the new *line_width* 835 ⟩   Used in section 829.

⟨ If all characters of the family fit relative to h, then **goto** *found*, otherwise **goto** *not_found* 955 ⟩   Used in section 953.

⟨If an alignment entry has just ended, take appropriate action 342⟩   Used in section 341.

⟨If an expanded code is present, reduce it and **goto** *start_cs* 355⟩   Used in sections 354 and 356.

⟨If dumping is not allowed, abort 1304⟩   Used in section 1302.

⟨If instruction *cur_i* is a kern with *cur_c*, attach the kern after *q*; or if it is a ligature with *cur_c*, combine noads *q* and *p* appropriately; then **return** if the cursor has moved past a noad, or **goto** *restart* 753⟩ Used in section 752.

⟨If no hyphens were found, **return** 902⟩   Used in section 895.

⟨If node *cur_p* is a legal breakpoint, call *try_break*; then update the active widths by including the glue in *glue_ptr*(*cur_p*) 868⟩   Used in section 866.

⟨If node *p* is a legal breakpoint, check if this break is the best known, and **goto** *done* if *p* is null or if the page-so-far is already too full to accept more stuff 972⟩   Used in section 970.

⟨If node *q* is a style node, change the style and **goto** *delete_q*; otherwise if it is not a noad, put it into the hlist, advance *q*, and **goto** *done*; otherwise set *s* to the size of noad *q*, set *t* to the associated type (*ord_noad* .. *inner_noad*), and set *pen* to the associated penalty 761⟩   Used in section 760.

⟨If node *r* is of type *delta_node*, update *cur_active_width*, set *prev_r* and *prev_prev_r*, then **goto** *resume* 832⟩   Used in section 829.

⟨If the current list ends with a box node, delete it from the list and make *cur_box* point to it; otherwise set *cur_box*: ← *null* 1080⟩   Used in section 1079.

⟨If the current page is empty and node *p* is to be deleted, **goto** *done1*; otherwise use node *p* to update the state of the current page; if this node is an insertion, **goto** *contribute*; otherwise if this node is not a legal breakpoint, **goto** *contribute* or *update_heights*; otherwise set *pi* to the penalty associated with this breakpoint 1000⟩   Used in section 997.

⟨If the cursor is immediately followed by the right boundary, **goto** *reswitch*; if it's followed by an invalid character, **goto** *big_switch*; otherwise move the cursor one step to the right and **goto** *main_lig_loop* 1036⟩   Used in section 1034.

⟨If the next character is a parameter number, make *cur_tok* a *match* token; but if it is a left brace, store '*left_brace*, *end_match*', set *hash_brace*, and **goto** *done* 476⟩   Used in section 474.

⟨If the preamble list has been traversed, check that the row has ended 792⟩   Used in section 791.

⟨If the right-hand side is a token parameter or token register, finish the assignment and **goto** *done* 1227⟩ Used in section 1226.

⟨If the string *hyph_word*[*h*] is less than *hc*[1..*hn*], **goto** *not_found*; but if the two strings are equal, set *hyf* to the hyphen positions and **goto** *found* 931⟩   Used in section 930.

⟨If the string *hyph_word*[*h*] is less than or equal to *s*, interchange (*hyph_word*[*h*], *hyph_list*[*h*]) with (*s*, *p*) 941⟩   Used in section 940.

⟨If there's a ligature or kern at the cursor position, update the data structures, possibly advancing *j*; continue until the cursor moves 909⟩   Used in section 906.

⟨If there's a ligature/kern command relevant to *cur_l* and *cur_r*, adjust the text appropriately; exit to *main_loop_wrapup* 1039⟩   Used in section 1034.

⟨If this font has already been loaded, set *f* to the internal font number and **goto** *common_ending* 1260⟩ Used in section 1257.

⟨If this *sup_mark* starts an expanded character like ^^A or ^^df, then **goto** *reswitch*, otherwise set *state*: ← *mid_line* 352⟩   Used in section 344.

⟨Ignore the fraction operation and complain about this ambiguous case 1183⟩   Used in section 1181.

⟨Implement \closeout 1354⟩   Used in section 1348.

⟨Implement \immediate 1376⟩   Used in section 1348.

⟨Implement \openout 1352⟩   Used in section 1348.

⟨Implement \savepos 1683⟩   Used in section 1682.

⟨Implement \setlanguage 1378⟩   Used in section 1348.

⟨Implement \special 1355⟩   Used in section 1348.

⟨Implement \write 1353⟩   Used in section 1348.

⟨Incorporate a whatsit node into a vbox 1360⟩   Used in section 669.

⟨Incorporate a whatsit node into an hbox 1361⟩   Used in section 651.

⟨ Incorporate box dimensions into the dimensions of the hbox that will contain it 653 ⟩   Used in sections 651,
        1726, and 1727.
⟨ Incorporate box dimensions into the dimensions of the vbox that will contain it 670 ⟩   Used in section 669.
⟨ Incorporate character dimensions into the dimensions of the hbox that will contain it, then move to the
        next node 654 ⟩   Used in sections 651 and 1726.
⟨ Incorporate glue into the horizontal totals 656 ⟩   Used in sections 651 and 1726.
⟨ Incorporate glue into the vertical totals 671 ⟩   Used in section 669.
⟨ Incorporate the various extended boxes into an hbox 1727 ⟩   Used in section 1726.
⟨ Increase the number of parameters in the last font 580 ⟩   Used in section 578.
⟨ Increase k until x can be multiplied by a factor of 2^{-k}, and adjust y accordingly 1638 ⟩   Used in section 1637.
⟨ Initialize definitions for baseline skips 1776 ⟩   Used in section 1749.
⟨ Initialize definitions for extended dimensions 1764 ⟩   Used in section 1749.
⟨ Initialize definitions for fonts 1791 ⟩   Used in section 1749.
⟨ Initialize definitions for labels 1798 ⟩   Used in section 1749.
⟨ Initialize for hyphenating a paragraph 891 ⟩   Used in section 863.
⟨ Initialize table entries (done by INITEX only) 164, 222, 228, 232, 240, 250, 258, 552, 946, 951, 1216, 1301, 1370, 1385,
        1502, 1526, 1544, 1583 ⟩   Used in section 8.
⟨ Initialize the current page, insert the \topskip glue ahead of p, and **goto** *resume* 1001 ⟩   Used in section 1000.
⟨ Initialize the input routines 331 ⟩   Used in section 1337.
⟨ Initialize the output routines 55, 61, 528, 533 ⟩   Used in section 1332.
⟨ Initialize the parameter node 1700 ⟩   Used in section 1698.
⟨ Initialize the print *selector* based on *interaction* 75 ⟩   Used in sections 1265 and 1337.
⟨ Initialize the special list heads and constant nodes 790, 797, 820, 981, 988 ⟩   Used in section 164.
⟨ Initialize variables as *ship_out* begins 617 ⟩   Used in section 640.
⟨ Initialize variables for ε-TₑX compatibility mode 1496 ⟩   Used in sections 1385 and 1387.
⟨ Initialize variables for ε-TₑX extended mode 1497, 1542 ⟩   Used in sections 1380 and 1387.
⟨ Initialize whatever TₑX might access 8 ⟩   Used in section 4.
⟨ Initiate input from new pseudo file 1439 ⟩   Used in section 1437.
⟨ Initiate or terminate input from a file 378 ⟩   Used in section 367.
⟨ Initiate the construction of an hbox or vbox, then **return** 1083 ⟩   Used in section 1079.
⟨ Input and store tokens from the next line of the file 483 ⟩   Used in section 482.
⟨ Input for \read from the terminal 484 ⟩   Used in section 483.
⟨ Input from external file, **goto** *restart* if no input found 343 ⟩   Used in section 341.
⟨ Input from token list, **goto** *restart* if end of list or if a parameter needs to be expanded 357 ⟩   Used in
        section 341.
⟨ Input the first line of *read_file*[m] 485 ⟩   Used in section 483.
⟨ Input the next line of *read_file*[m] 486 ⟩   Used in section 483.
⟨ Insert a delta node to prepare for breaks at *cur_p* 843 ⟩   Used in section 836.
⟨ Insert a delta node to prepare for the next active node 844 ⟩   Used in section 836.
⟨ Insert a dummy noad to be sub/superscripted 1177 ⟩   Used in section 1176.
⟨ Insert a new active node from *best_place*[*fit_class*] to *cur_p* 845 ⟩   Used in section 836.
⟨ Insert a new control sequence after p, then make p point to it 260 ⟩   Used in section 259.
⟨ Insert a new pattern into the linked trie 963 ⟩   Used in section 961.
⟨ Insert a new trie node between q and p, and make p point to it 964 ⟩   Used in sections 963, 1527, and 1528.
⟨ Insert a token containing *frozen_endv* 375 ⟩   Used in section 366.
⟨ Insert a token saved by \afterassignment, if any 1269 ⟩   Used in section 1211.
⟨ Insert glue for *split_top_skip* and set p: ← *null* 969 ⟩   Used in section 968.
⟨ Insert hyphens as specified in *hyph_list*[h] 932 ⟩   Used in section 931.
⟨ Insert macro parameter and **goto** *restart* 359 ⟩   Used in section 357.
⟨ Insert the appropriate mark text into the scanner 386 ⟩   Used in section 367.
⟨ Insert the current list into its environment 812 ⟩   Used in section 800.
⟨ Insert the pair (s, p) into the exception table 940 ⟩   Used in section 939.

⟨Insert the ⟨v_j⟩ template and **goto** *restart* 789⟩   Used in section 342.

⟨Insert token p into TEX's input 326⟩   Used in section 282.

⟨Interpret code c and **return** if done 84⟩   Used in section 83.

⟨Introduce new material from the terminal and **return** 87⟩   Used in section 84.

⟨Issue an error message if *cur_val* ← *fmem_ptr* 579⟩   Used in section 578.

⟨Justify the line ending at breakpoint *cur_p*, and append it to the current vertical list, together with associated penalties and other insertions 880⟩   Used in section 877.

⟨Last-minute procedures 1333, 1335, 1336, 1338, 1547⟩   Used in section 1330.

⟨Lengthen the preamble periodically 793⟩   Used in section 792.

⟨Let *cur_h* be the position of the first box, and set *leader_wd* + *lx* to the spacing between corresponding parts of boxes 627⟩   Used in section 626.

⟨Let *cur_v* be the position of the first box, and set *leader_ht* + *lx* to the spacing between corresponding parts of boxes 636⟩   Used in section 635.

⟨Let d be the natural width of node p; if the node is "visible," **goto** *found*; if the node is glue that stretches or shrinks, set v: ← *max_dimen* 1147⟩   Used in section 1146.

⟨Let d be the natural width of this glue; if stretching or shrinking, set v: ← *max_dimen*; **goto** *found* in the case of leaders 1148⟩   Used in section 1147.

⟨Let d be the width of the whatsit p 1362⟩   Used in section 1147.

⟨Let n be the largest legal code value, based on *cur_chr* 1233⟩   Used in section 1232.

⟨Link node p into the current page and **goto** *done* 998⟩   Used in section 997.

⟨Local variables for dimension calculations 450⟩   Used in section 448.

⟨Local variables for finishing 1198⟩

⟨Local variables for formatting calculations 315⟩   Used in section 311.

⟨Local variables for hyphenation 901, 912, 922, 929⟩   Used in section 895.

⟨Local variables for initialization 19, 163, 927⟩   Used in section 4.

⟨Local variables for line breaking 862, 893⟩   Used in section 815.

⟨Look ahead for another character, or leave *lig_stack* empty if there's none there 1038⟩   Used in section 1034.

⟨Look at all the marks in nodes before the break, and set the final link to *null* at the break 979⟩   Used in section 977.

⟨Look at the list of characters starting with x in font g; set f and c whenever a better character is found; **goto** *found* as soon as a large enough variant is encountered 708⟩   Used in section 707.

⟨Look at the other stack entries until deciding what sort of DVI command to generate; **goto** *found* if node p is a "hit" 611⟩   Used in section 607.

⟨Look at the variants of (z, x); set f and c whenever a better character is found; **goto** *found* as soon as a large enough variant is encountered 707⟩   Used in section 706.

⟨Look for parameter number or ## 479⟩   Used in section 477.

⟨Look for the word $hc[1..hn]$ in the exception table, and **goto** *found* (with *hyf* containing the hyphens) if an entry is found 930⟩   Used in section 923.

⟨Look up the characters of list n in the hash table, and set *cur_cs* 1452⟩   Used in section 1451.

⟨Look up the characters of list r in the hash table, and set *cur_cs* 374⟩   Used in section 372.

⟨Make a copy of node p in node r 205⟩   Used in section 204.

⟨Make a ligature node, if *ligature_present*; insert a null discretionary, if appropriate 1035⟩   Used in section 1034.

⟨Make a partial copy of the whatsit node p and make r point to it; set *words* to the number of initial words not yet copied 1358⟩   Used in section 206.

⟨Make a second pass over the mlist, removing all noads and inserting the proper spacing and penalties 760⟩   Used in section 726.

⟨Make final adjustments and **goto** *done* 576⟩   Used in section 562.

⟨Make node p look like a *char_node* and **goto** *reswitch* 652⟩   Used in sections 622, 651, 1147, and 1726.

⟨Make sure that f is in the proper range 1474⟩   Used in section 1467.

⟨Make sure that *page_max_depth* is not exceeded 1003⟩   Used in section 997.

⟨Make sure that *pi* is in the proper range 831⟩   Used in section 829.

⟨ Make the contribution list empty by setting its tail to *contrib_head* 995 ⟩   Used in section 1712.

⟨ Make the first 256 strings 48 ⟩   Used in section 47.

⟨ Make the height of box *y* equal to *h* 739 ⟩   Used in section 738.

⟨ Make the running dimensions in rule *q* extend to the boundaries of the alignment 806 ⟩   Used in section 805.

⟨ Make the unset node *r* into a *vlist_node* of height *w*, setting the glue as if the height were *t* 811 ⟩   Used in section 808.

⟨ Make the unset node *r* into an *hlist_node* of width *w*, setting the glue as if the width were *t* 810 ⟩   Used in section 808.

⟨ Make variable *b* point to a box for (f, c) 710 ⟩   Used in section 706.

⟨ Manufacture a control sequence name 372 ⟩   Used in section 367.

⟨ Math-only cases in non-math modes, or vice versa 1046 ⟩   Used in section 1045.

⟨ Merge the widths in the span nodes of *q* with those of *p*, destroying the span nodes of *q* 803 ⟩   Used in section 801.

⟨ Modify the end of the line to reflect the nature of the break and to include `\rightskip`; also set the proper value of *disc_break* 881 ⟩   Used in section 880.

⟨ Modify the glue specification in *main_p* according to the space factor 1044 ⟩   Used in section 1043.

⟨ Move down or output leaders 634 ⟩   Used in section 631.

⟨ Move node *p* to the current page; 997 ⟩

⟨ Move pointer *s* to the end of the current list, and set *replace_count*(*r*) appropriately 918 ⟩   Used in section 914.

⟨ Move right or output leaders 625 ⟩   Used in section 622.

⟨ Move the characters of a ligature node to *hu* and *hc*; but **goto** *done3* if they are not all letters 898 ⟩   Used in section 897.

⟨ Move the cursor past a pseudo-ligature, then **goto** *main_loop_lookahead* or *main_lig_loop* 1037 ⟩   Used in section 1034.

⟨ Move the data into *trie* 958 ⟩   Used in section 966.

⟨ Move to next line of file, or **goto** *restart* if there is no next line, or **return** if a `\read` line has finished 360 ⟩   Used in section 343.

⟨ Negate a boolean conditional and **goto** *reswitch* 1449 ⟩   Used in section 367.

⟨ Negate all three glue components of *cur_val* 431 ⟩   Used in sections 430 and 1464.

⟨ Nullify *width*(*q*) and the tabskip glue following this column 802 ⟩   Used in section 801.

⟨ Numbered cases for *debug_help* 1339 ⟩   Used in section 1338.

⟨ Open *tfm_file* for input 563 ⟩   Used in section 562.

⟨ Other local variables for *try_break* 830 ⟩   Used in section 829.

⟨ Output a box in a vlist 632 ⟩   Used in section 631.

⟨ Output a box in an hlist 623 ⟩   Used in section 622.

⟨ Output a leader box at *cur_h*, then advance *cur_h* by *leader_wd* + *lx* 628 ⟩   Used in section 626.

⟨ Output a leader box at *cur_v*, then advance *cur_v* by *leader_ht* + *lx* 637 ⟩   Used in section 635.

⟨ Output a rule in a vlist, **goto** *next_p* 633 ⟩   Used in section 631.

⟨ Output a rule in an hlist 624 ⟩   Used in section 622.

⟨ Output baseline skip definitions 1779 ⟩   Used in section 1750.

⟨ Output dimension definitions 1762 ⟩   Used in section 1750.

⟨ Output discretionary break definitions 1785 ⟩   Used in section 1750.

⟨ Output extended dimension definitions 1767 ⟩   Used in section 1750.

⟨ Output font definitions 1795 ⟩   Used in section 1750.

⟨ Output glue definitions 1773 ⟩   Used in section 1750.

⟨ Output integer definitions 1757 ⟩   Used in section 1750.

⟨ Output language definitions 1812 ⟩   Used in section 1750.

⟨ Output leaders in a vlist, **goto** *fin_rule* if a rule or to *next_p* if done 635 ⟩   Used in section 634.

⟨ Output leaders in an hlist, **goto** *fin_rule* if a rule or to *next_p* if done 626 ⟩   Used in section 625.

⟨ Output node *p* for *hlist_out* and move to the next node, maintaining the condition *cur_v* ← *base_line* 620 ⟩   Used in section 619.

⟨Output node p for *vlist_out* and move to the next node, maintaining the condition $cur\_h \leftarrow left\_edge$ 630⟩
        Used in section 629.

⟨Output page template definitions 1801⟩   Used in section 1750.

⟨Output parameter list definitions 1789⟩   Used in section 1750.

⟨Output statistics about this job 1334⟩   Used in section 1333.

⟨Output the font definitions for all fonts that were used 643⟩   Used in section 642.

⟨Output the font name whose internal number is f 603⟩   Used in section 602.

⟨Output the non-*char_node* p for *hlist_out* and move to the next node 622⟩   Used in section 620.

⟨Output the non-*char_node* p for *vlist_out* 631⟩   Used in section 630.

⟨Output the whatsit node p in a vlist 1367⟩   Used in section 631.

⟨Output the whatsit node p in an hlist 1368⟩   Used in section 622.

⟨Pack all stored *hyph_codes* 1529⟩   Used in section 966.

⟨Pack the family into *trie* relative to h 956⟩   Used in section 953.

⟨Package an unset box for the current column and record its width 796⟩   Used in section 791.

⟨Package the preamble list, to determine the actual tabskip glue amounts, and let p point to this prototype
        box 804⟩   Used in section 800.

⟨Perform the default output routine 1023⟩   Used in section 1012.

⟨Pontificate about improper alignment in display 1207⟩   Used in section 1206.

⟨Pop the condition stack 496⟩   Used in sections 498, 500, 509, and 510.

⟨Pop the expression stack and **goto** *found* 1473⟩   Used in section 1467.

⟨Prepare all the boxes involved in insertions to act as queues 1018⟩   Used in section 1014.

⟨Prepare to deactivate node r, and **goto** *deactivate* unless there is a reason to consider lines of text from r
        to cur_p 854⟩   Used in section 851.

⟨Prepare to insert a token that matches *cur_group*, and print what it is 1065⟩   Used in section 1064.

⟨Prepare to move a box or rule node to the current page, then **goto** *contribute* 1002⟩   Used in section 1000.

⟨Prepare to move whatsit p to the current page, then **goto** *contribute* 1365⟩   Used in section 1000.

⟨Print a short indication of the contents of node p 175⟩   Used in section 174.

⟨Print a symbolic description of the new break node 846⟩   Used in section 845.

⟨Print a symbolic description of this feasible break 856⟩   Used in section 855.

⟨Print either ‘`definition`’ or ‘`use`’ or ‘`preamble`’ or ‘`text`’, and insert tokens that should lead to
        recovery 339⟩   Used in section 338.

⟨Print location of current line 313⟩   Used in section 312.

⟨Print newly busy locations 171⟩   Used in section 167.

⟨Print string s as an error message 1283⟩   Used in section 1279.

⟨Print string s on the terminal 1280⟩   Used in section 1279.

⟨Print the banner line, including the date and time 536⟩   Used in section 534.

⟨Print the font identifier for $font(p)$ 267⟩   Used in sections 174 and 176.

⟨Print the help information and **goto** *resume* 89⟩   Used in section 84.

⟨Print the list between *printed_node* and cur_p, then set $printed\_node: \leftarrow cur\_p$ 857⟩   Used in section 856.

⟨Print the menu of available options 85⟩   Used in section 84.

⟨Print the result of command c 472⟩   Used in section 470.

⟨Print two lines using the tricky pseudoprinted information 317⟩   Used in section 312.

⟨Print type of token list 314⟩   Used in section 312.

⟨Process an active-character control sequence and set $state: \leftarrow mid\_line$ 353⟩   Used in section 344.

⟨Process an expression and **return** 1464⟩   Used in section 424.

⟨Process node-or-noad q as much as possible in preparation for the second pass of *mlist_to_hlist*, then move
        to the next item in the mlist 727⟩   Used in section 726.

⟨Process whatsit p in *vert_break* loop, **goto** *not_found* 1366⟩   Used in section 973.

⟨Prune the current list, if necessary, until it contains only *char_node*, *kern_node*, *hlist_node*, *vlist_node*,
        rule_node, and *ligature_node* items; set n to the length of the list, and set q to the list's tail 1121⟩
        Used in section 1119.

⟨Prune unwanted nodes at the beginning of the next line 879⟩   Used in section 877.

⟨Pseudoprint the line 318⟩   Used in section 312.

⟨Pseudoprint the token list 319⟩   Used in section 312.

⟨Push the condition stack 495⟩   Used in section 498.

⟨Push the expression stack and **goto** *restart* 1472⟩   Used in section 1469.

⟨Put each of TEX's primitives into the hash table 226, 230, 238, 248, 265, 334, 376, 384, 411, 416, 468, 487, 491, 553, 780, 983, 1052, 1058, 1071, 1088, 1107, 1114, 1141, 1156, 1169, 1178, 1188, 1208, 1219, 1222, 1230, 1250, 1254, 1262, 1272, 1277, 1286, 1291, 1344⟩   Used in section 1336.

⟨Put help message on the transcript file 90⟩   Used in section 82.

⟨Put the characters $hu[i + 1..]$ into $post\_break(r)$, appending to this list and to $major\_tail$ until synchronization has been achieved 916⟩   Used in section 914.

⟨Put the characters $hu[l .. i]$ and a hyphen into $pre\_break(r)$ 915⟩   Used in section 914.

⟨Put the fraction into a box with its delimiters, and make $new\_hlist(q)$ point to it 748⟩   Used in section 743.

⟨Put the \leftskip glue at the left and detach this line 887⟩   Used in section 880.

⟨Put the optimal current page into box 255, update $first\_mark$ and bot_mark, append insertions to their boxes, and put the remaining nodes back on the contribution list 1014⟩   Used in section 1012.

⟨Put the (positive) 'at' size into s 1259⟩   Used in section 1258.

⟨Put the \rightskip glue after node q 886⟩   Used in section 881.

⟨Read and check the font data; *abort* if the TFM file is malformed; if there's no room for this font, say so and **goto** *done*; otherwise $incr(font\_ptr)$ and **goto** *done* 562⟩   Used in section 560.

⟨Read box dimensions 571⟩   Used in section 562.

⟨Read character data 569⟩   Used in section 562.

⟨Read extensible character recipes 574⟩   Used in section 562.

⟨Read font parameters 575⟩   Used in section 562.

⟨Read ligature/kern program 573⟩   Used in section 562.

⟨Read next line of file into $buffer$, or **goto** *restart* if the file has ended 362⟩   Used in section 360.

⟨Read the first line of the new file 538⟩   Used in section 537.

⟨Read the TFM header 568⟩   Used in section 562.

⟨Read the TFM size fields 565⟩   Used in section 562.

⟨Readjust the height and depth of cur_box, for \vtop 1087⟩   Used in section 1086.

⟨Reconstitute nodes for the hyphenated word, inserting discretionary hyphens 913⟩   Used in section 903.

⟨Record a new feasible break 855⟩   Used in section 851.

⟨Record the bottom mark 1725⟩   Used in section 1712.

⟨Recover from an unbalanced output routine 1027⟩   Used in section 1026.

⟨Recover from an unbalanced write command 1373⟩   Used in section 1372.

⟨Recycle node p 999⟩   Used in section 997.

⟨Reduce to the case that $a, c \geq 0$, $b, d > 0$ 1664⟩   Used in section 1663.

⟨Reduce to the case that $f \geq 0$ and $q > 0$ 1644⟩   Used in section 1643.

⟨Remove the last box, unless it's part of a discretionary 1081⟩   Used in section 1080.

⟨Replace nodes $ha .. hb$ by a sequence of nodes that includes the discretionary hyphens 903⟩   Used in section 895.

⟨Replace the tail of the list by p 1187⟩   Used in section 1186.

⟨Replace z by z' and compute α, β 572⟩   Used in section 571.

⟨Report a runaway argument and abort 396⟩   Used in sections 392 and 399.

⟨Report a tight hbox and **goto** *common_ending*, if this box is sufficiently bad 667⟩   Used in section 664.

⟨Report a tight vbox and **goto** *common_ending*, if this box is sufficiently bad 678⟩   Used in section 676.

⟨Report an extra right brace and **goto** *resume* 395⟩   Used in section 392.

⟨Report an improper use of the macro and abort 398⟩   Used in section 397.

⟨Report an overfull hbox and **goto** *common_ending*, if this box is sufficiently bad 666⟩   Used in section 664.

⟨Report an overfull vbox and **goto** *common_ending*, if this box is sufficiently bad 677⟩   Used in section 676.

⟨Report an underfull hbox and **goto** *common_ending*, if this box is sufficiently bad 660⟩   Used in section 658.

⟨Report an underfull vbox and **goto** *common_ending*, if this box is sufficiently bad 674⟩   Used in section 673.

⟨Report overflow of the input buffer, and abort 35⟩   Used in sections 31, 1440, and 1887.

⟨ Report that an invalid delimiter code is being changed to null; set *cur_val*: ← 0 1161 ⟩   Used in section 1160.

⟨ Report that the font won't be loaded 561 ⟩   Used in section 560.

⟨ Report that this dimension is out of range 460 ⟩   Used in section 448.

⟨ Resume the page builder after an output routine has come to an end 1026 ⟩   Used in section 1100.

⟨ Reverse the links of the relevant passive nodes, setting *cur_p* to the first breakpoint 878 ⟩   Used in section 877.

⟨ Scan a control sequence and set *state*: ← *skip_blanks* or *mid_line* 354 ⟩   Used in section 344.

⟨ Scan a factor *f* of type *o* or start a subexpression 1469 ⟩   Used in section 1467.

⟨ Scan a numeric constant 444 ⟩   Used in section 440.

⟨ Scan a parameter until its delimiter string has been found; or, if *s* ← *null*, simply scan the delimiter string 392 ⟩   Used in section 391.

⟨ Scan a subformula enclosed in braces and **return** 1153 ⟩   Used in section 1151.

⟨ Scan ahead in the buffer until finding a nonletter; if an expanded code is encountered, reduce it and **goto** *start_cs*; otherwise if a multiletter control sequence is found, adjust *cur_cs* and *loc*, and **goto** *found* 356 ⟩   Used in section 354.

⟨ Scan an alphabetic character code into *cur_val* 442 ⟩   Used in section 440.

⟨ Scan an optional space 443 ⟩   Used in sections 442, 448, 455, and 1200.

⟨ Scan and build the body of the token list; **goto** *found* when finished 477 ⟩   Used in section 473.

⟨ Scan and build the parameter part of the macro definition 474 ⟩   Used in section 473.

⟨ Scan and evaluate an expression *e* of type *l* 1467 ⟩   Used in section 1466.

⟨ Scan decimal fraction 452 ⟩   Used in section 448.

⟨ Scan file name in the buffer 531 ⟩   Used in section 530.

⟨ Scan for all other units and adjust *cur_val* and *f* accordingly; **goto** *done* in the case of scaled points 458 ⟩   Used in section 453.

⟨ Scan for **fil** units; **goto** *attach_fraction* if found 454 ⟩   Used in section 453.

⟨ Scan for **mu** units and **goto** *attach_fraction* 456 ⟩   Used in section 453.

⟨ Scan for units that are internal dimensions; **goto** *attach_sign* with *cur_val* set if found 455 ⟩   Used in section 453.

⟨ Scan preamble text until *cur_cmd* is *tab_mark* or *car_ret*, looking for changes in the tabskip glue; append an alignrecord to the preamble list 779 ⟩   Used in section 777.

⟨ Scan the argument for command *c* 471 ⟩   Used in section 470.

⟨ Scan the font size specification 1258 ⟩   Used in section 1257.

⟨ Scan the next operator and set *o* 1468 ⟩   Used in section 1467.

⟨ Scan the parameters and make *link*(*r*) point to the macro body; but **return** if an illegal \par is detected 391 ⟩   Used in section 389.

⟨ Scan the preamble and record it in the *preamble* list 777 ⟩   Used in section 774.

⟨ Scan the template ⟨*u_j*⟩, putting the resulting token list in *hold_head* 783 ⟩   Used in section 779.

⟨ Scan the template ⟨*v_j*⟩, putting the resulting token list in *hold_head* 784 ⟩   Used in section 779.

⟨ Scan units and set *cur_val* to $x \cdot (cur\_val + f/2^{16})$, where there are *x* sp per unit; **goto** *attach_sign* if the units are internal 453 ⟩   Used in section 448.

⟨ Search *eqtb* for equivalents equal to *p* 255 ⟩   Used in section 172.

⟨ Search *hyph_list* for pointers to *p* 933 ⟩   Used in section 172.

⟨ Search *save_stack* for equivalents that point to *p* 285 ⟩   Used in section 172.

⟨ Select the appropriate case and **return** or **goto** *common_ending* 509 ⟩   Used in section 501.

⟨ Set initial values of key variables 21, 23, 24, 74, 77, 80, 97, 166, 215, 254, 257, 272, 287, 383, 439, 481, 490, 551, 556, 593, 596, 606, 648, 662, 685, 771, 928, 990, 1033, 1267, 1282, 1300, 1343, 1435, 1501, 1520, 1532 ⟩   Used in section 8.

⟨ Set line length parameters in preparation for hanging indentation 849 ⟩   Used in section 848.

⟨ Set the glue in all the unset boxes of the current list 805 ⟩   Used in section 800.

⟨ Set the glue in node *r* and change it from an unset node 808 ⟩   Used in section 807.

⟨ Set the unset box *q* and the unset boxes in it 807 ⟩   Used in section 805.

⟨ Set the value of *b* to the badness for shrinking the line, and compute the corresponding *fit_class* 853 ⟩   Used in section 851.

⟨ Set the value of b to the badness for stretching the line, and compute the corresponding *fit_class* 852 ⟩
  Used in section 851.

⟨ Set the value of *output_penalty* 1013 ⟩   Used in section 1012.

⟨ Set up data structures with the cursor following position j 908 ⟩   Used in section 906.

⟨ Set up the values of *cur_size* and *cur_mu*, based on *cur_style* 703 ⟩   Used in sections 720, 726, 727, 730, 754,
  760, 762, and 763.

⟨ Set variable c to the current escape character 243 ⟩   Used in section 63.

⟨ Set variable w to indicate if this case should be reported 1459 ⟩   Used in sections 1458 and 1460.

⟨ Set *last_saved_xpos* and *last_saved_ypos* with transformed coordinates 1674 ⟩   Used in section 1687.

⟨ Ship box p out 640 ⟩

⟨ Show equivalent n, in region 1 or 2 223 ⟩   Used in section 252.

⟨ Show equivalent n, in region 3 229 ⟩   Used in section 252.

⟨ Show equivalent n, in region 4 233 ⟩   Used in section 252.

⟨ Show equivalent n, in region 5 242 ⟩   Used in section 252.

⟨ Show equivalent n, in region 6 251 ⟩   Used in section 252.

⟨ Show the auxiliary field, a 219 ⟩   Used in section 218.

⟨ Show the box context 1413 ⟩   Used in section 1411.

⟨ Show the box packaging info 1412 ⟩   Used in section 1411.

⟨ Show the current contents of a box 1296 ⟩   Used in section 1293.

⟨ Show the current meaning of a token, then **goto** *common_ending* 1294 ⟩   Used in section 1293.

⟨ Show the current value of some parameter or register, then **goto** *common_ending* 1297 ⟩   Used in section 1293.

⟨ Show the font identifier in *eqtb*[n] 234 ⟩   Used in section 233.

⟨ Show the halfword code in *eqtb*[n] 235 ⟩   Used in section 233.

⟨ Show the status of the current page 986 ⟩   Used in section 218.

⟨ Show the text of the macro being expanded 401 ⟩   Used in section 389.

⟨ Simplify a trivial box 721 ⟩   Used in section 720.

⟨ Skip to \else or \fi, then **goto** *common_ending* 500 ⟩   Used in section 498.

⟨ Skip to node *ha*, or **goto** *done1* if no hyphenation should be attempted 896 ⟩   Used in section 894.

⟨ Skip to node *hb*, putting letters into *hu* and *hc* 897 ⟩   Used in section 894.

⟨ Sort p into the list starting at *rover* and advance p to *rlink*(p) 132 ⟩   Used in section 131.

⟨ Sort the hyphenation op tables into proper order 945 ⟩   Used in section 952.

⟨ Split off part of a vertical box, make *cur_box* point to it 1082 ⟩   Used in section 1079.

⟨ Squeeze the equation as much as possible 1201 ⟩

⟨ Start a new current page 991 ⟩   Used in sections 215 and 1017.

⟨ Store *cur_box* in a box register 1077 ⟩   Used in section 1075.

⟨ Store maximum values in the *hyf* table 924 ⟩   Used in section 923.

⟨ Store *save_stack*[*save_ptr*] in *eqtb*[p], unless *eqtb*[p] holds a global value 283 ⟩   Used in section 282.

⟨ Store all current *lc_code* values 1528 ⟩   Used in section 1527.

⟨ Store hyphenation codes for current language 1527 ⟩   Used in section 960.

⟨ Store the current token, but **goto** *resume* if it is a blank space that would become an undelimited
  parameter 393 ⟩   Used in section 392.

⟨ Subtract glue from *break_width* 838 ⟩   Used in section 837.

⟨ Subtract the width of node v from *break_width* 841 ⟩   Used in section 840.

⟨ Suppress double quotes in braced input file name 1865 ⟩   Used in section 1864.

⟨ Suppress empty pages if requested 1714 ⟩   Used in section 1712.

⟨ Suppress expansion of the next token 369 ⟩   Used in section 367.

⟨ Swap the subscript and superscript into box x 742 ⟩   Used in section 738.

⟨ Switch to a larger accent if available and appropriate 740 ⟩   Used in section 738.

⟨ Switch *hsize* and *vsize* to extended dimensions 1719 ⟩   Used in section 1749.

⟨ Tell the user what has run away and try to recover 338 ⟩   Used in section 336.

⟨ Terminate the current conditional and skip to \fi 510 ⟩   Used in section 367.

⟨ Test box register status 505 ⟩   Used in section 501.

⟨Test if an integer is odd 504⟩   Used in section 501.

⟨Test if two characters match 506⟩   Used in section 501.

⟨Test if two macro texts match 508⟩   Used in section 507.

⟨Test if two tokens match 507⟩   Used in section 501.

⟨Test relation between integers or dimensions 503⟩   Used in section 501.

⟨The em width for *cur_font* 558⟩   Used in section 455.

⟨The x-height for *cur_font* 559⟩   Used in section 455.

⟨Tidy up the parameter just scanned, and tuck it away 400⟩   Used in section 392.

⟨Transfer node *p* to the adjustment list 655⟩   Used in sections 651 and 1726.

⟨Transplant the post-break list 884⟩   Used in section 882.

⟨Transplant the pre-break list 885⟩   Used in section 882.

⟨Treat *cur_chr* as an active character 1152⟩   Used in sections 1151 and 1155.

⟨Try the final line break at the end of the paragraph, and **goto** *done* if the desired breakpoints have been found 873⟩   Used in section 863.

⟨Try to allocate within node *p* and its physical successors, and **goto** *found* if allocation was possible 127⟩   Used in section 125.

⟨Try to break after a discretionary fragment, then **goto** *done5* 869⟩   Used in section 866.

⟨Try to get a different log file name 535⟩   Used in section 534.

⟨Try to recover from mismatched \right 1192⟩   Used in section 1191.

⟨Types in the outer block 18, 25, 38, 101, 109, 113, 150, 212, 269, 300, 548, 594, 920, 925, 1410, 1640⟩   Used in section 4.

⟨Undump a couple more things and the closing check word 1327⟩   Used in section 1303.

⟨Undump constants for consistency check 1308⟩   Used in section 1303.

⟨Undump regions 1 to 6 of *eqtb* 1317⟩   Used in section 1314.

⟨Undump the PRoTE state 1546⟩   Used in section 1308.

⟨Undump the ε-TEX state 1387⟩   Used in section 1308.

⟨Undump the array info for internal font number *k* 1323⟩   Used in section 1321.

⟨Undump the dynamic memory 1312⟩   Used in section 1303.

⟨Undump the font information 1321⟩   Used in section 1303.

⟨Undump the hash table 1319⟩   Used in section 1314.

⟨Undump the hyphenation tables 1325⟩   Used in section 1303.

⟨Undump the string pool 1310⟩   Used in section 1303.

⟨Undump the table of equivalents 1314⟩   Used in section 1303.

⟨Undump the ROM array 1587⟩   Used in section 1308.

⟨Update the active widths, since the first active node has been deleted 861⟩   Used in section 860.

⟨Update the current height and depth measurements with respect to a glue or kern node *p* 976⟩   Used in section 972.

⟨Update the current marks for *fire_up* 1514⟩   Used in section 1014.

⟨Update the current marks for *vsplit* 1511⟩   Used in section 979.

⟨Update the current page measurements with respect to the glue or kern specified by node *p* 1004⟩   Used in section 997.

⟨Update the value of *printed_node* for symbolic displays 858⟩   Used in section 829.

⟨Update the values of *first_mark* and *bot_mark* 1016⟩   Used in section 1014.

⟨Update the values of *last_glue*, *last_penalty*, and *last_kern* 996⟩   Used in section 994.

⟨Update the values of *max_h* and *max_v*; but if the page is too large, **goto** *done* 641⟩   Used in section 640.

⟨Update width entry for spanned columns 798⟩   Used in section 796.

⟨Use code *c* to distinguish between generalized fractions 1182⟩   Used in section 1181.

⟨Use node *p* to update the current height and depth measurements; if this node is not a legal breakpoint, **goto** *not_found* or *update_heights*, otherwise set *pi* to the associated penalty at the break 973⟩   Used in section 972.

⟨Use size fields to allocate font information 566⟩   Used in section 562.

⟨Wipe out the whatsit node *p* and **goto** *done* 1359⟩   Used in section 202.

⟨ Wrap up the box specified by node r, splitting node p if called for; set *wait*: ← *true* if node p holds a remainder after splitting 1021 ⟩   Used in section 1020.

⟨ PRoTE initializations 1569, 1575, 1636, 1651, 1673, 1679 ⟩   Used in section 1547.

⟨ TEX Live auxiliary functions 1849, 1862, 1866, 1869, 1870, 1875, 1879, 1882, 1886, 1887, 1890, 1891, 1896 ⟩   Used in section 1845.

⟨ TEX Live functions 1847, 1853, 1889, 1892 ⟩   Used in section 1845.

⟨ activate configuration lines 1876 ⟩   Used in section 1847.

⟨ cases to output content nodes 1805, 1806, 1813, 1815, 1817, 1818, 1819, 1820, 1821, 1822, 1824, 1825, 1834 ⟩   Used in section 1803.

⟨ cases to output whatsit content nodes 1800, 1810, 1826, 1827, 1828, 1829, 1830, 1831, 1839, 1840 ⟩   Used in section 1825.

⟨ enable the generation of input files 1893 ⟩   Used in section 1847.

⟨ explain the command line 1850 ⟩   Used in section 1849.

⟨ explain the options 1851 ⟩   Used in section 1849.

⟨ fix simple use of parshape 1702 ⟩   Used in section 1701.

⟨ handle the options 1857, 1858, 1859, 1860, 1861, 1874, 1877 ⟩   Used in section 1853.

⟨ insert an initial language node 1811 ⟩   Used in section 1739.

⟨ output a character node 1804 ⟩   Used in section 1803.

⟨ output stream content 1823 ⟩   Used in section 1822.

⟨ output stream definitions 1802 ⟩   Used in section 1801.

⟨ parse options 1855 ⟩   Used in section 1847.

⟨ record the names of files in optional sections 1741 ⟩   Used in section 1740.

⟨ record `texmf.cnf` 1872 ⟩   Used in section 1855.

⟨ set defaults from the `texmf.cfg` file 1881 ⟩   Used in section 1847.

⟨ set the format name 1885 ⟩   Used in section 1847.

⟨ set the input file name 1880 ⟩   Used in section 1847.

⟨ set the program and engine name 1878 ⟩   Used in section 1847.
