System-dependent changes 222	381
Index	382

The preparation of this report was supported in part by the National Science Foundation under grants IST-8201926, MCS-8300984, and CCR-8610181, and by the System Development Foundation. 'TEX' is a trademark of the American Mathematical Society. 'METAFONT' is a trademark of Addison-Wesley Publishing Company.

1. Introduction. The GFtoDVI utility program reads binary generic font ("GF") files that are produced by font compilers such as METAFONT, and converts them into device-independent ("DVI") files that can be printed to give annotated hardcopy proofs of the character shapes. The annotations are specified by the comparatively simple conventions of plain METAFONT; i.e., there are mechanisms for labeling chosen points and for superimposing horizontal or vertical rules on the enlarged character shapes.

The purpose of GFtoDVI is simply to make proof copies; it does not exhaustively test the validity of a GF file, nor do its algorithms much resemble the algorithms that are typically used to prepare font descriptions for commercial typesetting equipment. Another program, GFtype, is available for validity checking; GFtype also serves as a model of programs that convert fonts from GF format to some other coding scheme.

The banner string defined here should be changed whenever GFtoDVI gets modified.

define  $banner \equiv \text{This}_{\Box}\text{GFtoDVI},_{\Box}\text{Version}_3.0^{\circ} \{ \text{printed when the program starts} \}$ 

2. This program is written in standard Pascal, except where it is necessary to use extensions; for example, GFtoDVI must read files whose names are dynamically specified, and such a task would be impossible in pure Pascal. All places where nonstandard constructions are used have been listed in the index under "system dependencies."

Another exception to standard Pascal occurs in the use of default branches in **case** statements; the conventions of **TANGLE**, **WEAVE**, etc., have been followed.

**define** *othercases*  $\equiv$  *others*: { default for cases not listed explicitly } **define** *endcases*  $\equiv$  **end** { follows the default case in an extended **case** statement } **format** *othercases*  $\equiv$  *else* **format** *endcases*  $\equiv$  *end* 

**3.** The main input and output files are not mentioned in the program header, because their external names will be determined at run time (e.g., by interpreting the command line that invokes this program). Error messages and other remarks are written on the *output* file, which the user may choose to assign to the terminal if the system permits it.

The term *print* is used instead of *write* when this program writes on the *output* file, so that all such output can be easily deflected.

```
define print(#) \equiv write(#)

define print_ln(#) \equiv write_ln(#)

define print_nl(#) \equiv begin write_ln; write(#); end

program GF_{to_DVI(output)};

label (Labels in the outer block 4)

const (Constants in the outer block 5)

type (Types in the outer block 9)

var (Globals in the outer block 12)

procedure initialize; { this procedure gets things started properly }

var i, j, m, n: integer; { loop indices for initializations }

begin print_ln(banner);

(Set initial values 13)

end;
```

4. If the program has to stop prematurely, it goes to the 'final\_end'.define final\_end = 9999 { label for the end of it all }

 $\langle \text{Labels in the outer block } 4 \rangle \equiv final_end;$ 

This code is used in section 3.

5. The following parameters can be changed at compile time to extend or reduce GFtoDVI's capacity.

 $\langle \text{Constants in the outer block } 5 \rangle \equiv$ 

max\_labels = 2000; { maximum number of labels and dots and rules per character }
pool\_size = 10000; { maximum total length of labels and other strings }
max\_strings = 1100; { maximum number of labels and other strings }
terminal\_line\_length = 150;
{ maximum number of characters input in a single line of input from the terminal }
file\_name\_size = 50; { a file name shouldn't be longer than this }
font\_mem\_size = 2000; { space for font metric data }
dvi\_buf\_size = 800; { size of the output buffer; must be a multiple of 8 }
widest\_row = 8192; { maximum number of pixels per row }

 $lig_lookahead = 20;$  {size of stack used when inserting ligature characters }

This code is used in section 3.

6. Labels are given symbolic names by the following definitions, so that occasional **goto** statements will be meaningful. We insert the label '*exit*:' just before the '**end**' of a procedure in which we have used the '**return**' statement defined below; the label '*reswitch*' is occasionally used just prior to a **case** statement in which some cases change the conditions and we wish to branch to the newly applicable case. Loops that are set up with the **loop** construction defined below are commonly exited by going to '*done*' or to '*found*' or to '*not\_found*', and they are sometimes repeated by going to '*continue*'.

Incidentally, this program never declares a label that isn't actually used, because some fussy Pascal compilers will complain about redundant labels.

define exit = 10 {go here to leave a procedure }define reswitch = 21 {go here to start a case statement again }define continue = 22 {go here to resume a loop }define done = 30 {go here to exit a loop }define done1 = 31 {like done, when there is more than one loop }define found = 40 {go here when you've found it }define  $not_found = 45$  {go here when you've found nothing }

7. Here are some macros for common programming idioms.

define  $incr(\#) \equiv \# \leftarrow \# + 1$  { increase a variable by unity } define  $decr(\#) \equiv \# \leftarrow \# - 1$  { decrease a variable by unity } define  $loop \equiv while true do$  { repeat over and over until a goto happens } format  $loop \equiv xclause$  { WEB's xclause acts like 'while true do' } define  $do\_nothing \equiv$  { empty statement } define return  $\equiv$  goto exit { terminate a procedure call } format return  $\equiv nil$  { WEB will henceforth say return instead of return }

8. If the GF file is badly malformed, the whole process must be aborted; GFtoDVI will give up, after issuing an error message about the symptoms that were noticed.

Such errors might be discovered inside of subroutines inside of subroutines, so a procedure called *jump\_out* has been introduced. This procedure, which simply transfers control to the label *final\_end* at the end of the program, contains the only non-local **goto** statement in **GFtoDVI**.

define abort(#) ≡ begin print(´\_',#); jump\_out; end define bad\_gf(#) ≡ abort(`Bad\_GF\_file:\_',#,´!\_(at\_byte\_`, cur\_loc - 1:1,`)`) procedure jump\_out; begin goto final\_end; end; 9. As in  $T_EX$  and METAFONT, this program deals with numeric quantities that are integer multiples of  $2^{16}$ , and calls them *scaled*.

**define**  $unity \equiv 200000 \{ scaled representation of 1.0 \}$ 

 $\langle \text{Types in the outer block } 9 \rangle \equiv$ 

 $scaled = integer; \{ fixed-point numbers \}$ 

See also sections 10, 11, 45, 52, 70, 79, 104, and 139.

This code is used in section 3.

10. The character set. Like all programs written with the WEB system, GFtoDVI can be used with any character set. But it uses ASCII code internally, because the programming for portable input-output is easier when a fixed internal code is used. Furthermore, both GF and DVI files use ASCII code for file names and certain other strings. The next few sections of GFtoDVI have therefore been copied from the analogous ones in the WEB system routines.

 $\langle \text{Types in the outer block } 9 \rangle + \equiv$ ASCII\_code = 0...255; { eight-bit numbers, a subrange of the integers }

11. The original Pascal compiler was designed in the late 60s, when six-bit character sets were common, so it did not make provision for lowercase letters. Nowadays, of course, we need to deal with both capital and small letters in a convenient way. So we shall assume that the Pascal system being used for GFtoDVI has a character set containing at least the standard visible ASCII characters ("!" through "~"). If additional characters are present, GFtoDVI can be configured to work with them too.

Some Pascal compilers use the original name *char* for the data type associated with the characters in text files, while other Pascals consider *char* to be a 64-element subrange of a larger data type that has some other name. In order to accommodate this difference, we shall use the name *text\_char* to stand for the data type of the characters in the output file. We shall also assume that *text\_char* consists of the elements  $chr(first_text_char)$  through  $chr(last_text_char)$ , inclusive. The following definitions should be adjusted if necessary.

define  $text\_char \equiv char$  { the data type of characters in text files } define  $first\_text\_char = 0$  { ordinal number of the smallest element of  $text\_char$  } define  $last\_text\_char = 255$  { ordinal number of the largest element of  $text\_char$  }  $\langle Types in the outer block 9 \rangle + \equiv$  $text\_file = packed file of text\_char;$ 

12. The GFtoDVI processor converts between ASCII code and the user's external character set by means of arrays *xord* and *xchr* that are analogous to Pascal's *ord* and *chr* functions.

 $\langle \text{Globals in the outer block } 12 \rangle \equiv xord: \operatorname{array} [text_char] of ASCII_code; { specifies conversion of input characters } xchr: \operatorname{array} [ASCII_code] of text_char; { specifies conversion of output characters } See also sections 16, 18, 37, 46, 48, 49, 53, 71, 76, 80, 86, 87, 93, 96, 102, 105, 117, 127, 134, 140, 149, 155, 158, 160, 166, 168, 174, 182, 183, 207, 211, 212, and 220.$ 

This code is used in section 3.

**13.** Under our assumption that the visible characters of standard ASCII are all present, the following assignment statements initialize the *xchr* array properly, without needing any system-dependent changes.

$$\langle \text{Set initial values } 13 \rangle \equiv$$

 $xchr['40] \leftarrow ['41] \leftarrow [!]; xchr['42] \leftarrow ["]; xchr['43] \leftarrow [#]; xchr['44] \leftarrow [$;$  $xchr['45] \leftarrow '\%'; xchr['46] \leftarrow '\&'; xchr['47] \leftarrow ''';$  $xchr[50] \leftarrow (; xchr[51] \leftarrow ); xchr[52] \leftarrow *; xchr[53] \leftarrow +; xchr[54] \leftarrow ,;$  $xchr['55] \leftarrow -; xchr['56] \leftarrow .; xchr['57] \leftarrow .';$  $xchr['60] \leftarrow 1^{;} xchr['61] \leftarrow 1^{;} xchr['62] \leftarrow 2^{;} xchr['63] \leftarrow 3^{;} xchr['64] \leftarrow 4^{;}$  $xchr[65] \leftarrow 5; xchr[66] \leftarrow 6; xchr[67] \leftarrow 7;$  $xchr['70] \leftarrow `8`; xchr['71] \leftarrow `9`; xchr['72] \leftarrow `:`; xchr['73] \leftarrow `;`; xchr['74] \leftarrow `<`;$  $xchr['75] \leftarrow `=`; xchr['76] \leftarrow `>`; xchr['77] \leftarrow `?`;$  $xchr['100] \leftarrow [0^{\circ}; xchr['101] \leftarrow [A^{\circ}; xchr['102] \leftarrow [B^{\circ}; xchr['103] \leftarrow [C^{\circ}; xchr['104] \leftarrow [D^{\circ}; xchr['1$  $xchr['105] \leftarrow `E`; xchr['106] \leftarrow `F`; xchr['107] \leftarrow `G`;$  $xchr['110] \leftarrow `H`; xchr['111] \leftarrow `I`; xchr['112] \leftarrow `J`; xchr['113] \leftarrow `K`; xchr['114] \leftarrow `L`;$  $xchr['115] \leftarrow \mathsf{M}; xchr['116] \leftarrow \mathsf{N}; xchr['117] \leftarrow \mathsf{O};$  $xchr['120] \leftarrow `P`; xchr['121] \leftarrow `Q`; xchr['122] \leftarrow `R`; xchr['123] \leftarrow `S`; xchr['124] \leftarrow `T';$  $xchr['125] \leftarrow `U`; xchr['126] \leftarrow `V`; xchr['127] \leftarrow `W`;$  $xchr['130] \leftarrow `X`; xchr['131] \leftarrow `Y`; xchr['132] \leftarrow `Z`; xchr['133] \leftarrow `[`; xchr['134] \leftarrow `\`;$  $xchr['135] \leftarrow `]`; xchr['136] \leftarrow ```; xchr['137] \leftarrow `_`;$  $xchr['140] \leftarrow ```; xchr['141] \leftarrow `a`; xchr['142] \leftarrow `b`; xchr['143] \leftarrow `c`; xchr['144] \leftarrow `d`;$  $xchr['145] \leftarrow \text{`e'}; xchr['146] \leftarrow \text{`f'}; xchr['147] \leftarrow \text{`g'};$  $xchr[150] \leftarrow h^{+}; xchr[151] \leftarrow i^{+}; xchr[152] \leftarrow j^{+}; xchr[153] \leftarrow k^{+}; xchr[154] \leftarrow 1^{+};$  $xchr['155] \leftarrow \text{`m'}; xchr['156] \leftarrow \text{`n'}; xchr['157] \leftarrow \text{`o'};$  $xchr['160] \leftarrow \mathbf{\hat{p}}; xchr['161] \leftarrow \mathbf{\hat{q}}; xchr['162] \leftarrow \mathbf{\hat{r}}; xchr['163] \leftarrow \mathbf{\hat{s}}; xchr['164] \leftarrow \mathbf{\hat{t}};$  $xchr['165] \leftarrow `u`; xchr['166] \leftarrow `v`; xchr['167] \leftarrow `w`;$  $xchr['170] \leftarrow \mathbf{x}; xchr['171] \leftarrow \mathbf{y}; xchr['172] \leftarrow \mathbf{z}; xchr['173] \leftarrow \mathbf{z}; xchr['174] \leftarrow \mathbf{z};$  $xchr['175] \leftarrow ``; xchr['176] \leftarrow ```;$ 

See also sections 14, 15, 54, 97, 103, 106, 118, 126, and 142. This code is used in section 3.

14. Here now is the system-dependent part of the character set. If GFtoDVI is being implemented on a garden-variety Pascal for which only standard ASCII codes will appear in the input and output files, you don't need to make any changes here. But if you have, for example, an extended character set like the one in Appendix C of *The T<sub>F</sub>Xbook*, the first line of code in this module should be changed to

for  $i \leftarrow 0$  to '37 do  $xchr[i] \leftarrow chr(i)$ ;

WEB's character set is essentially identical to  $T_{E}X$ 's.

 $\langle \text{Set initial values } 13 \rangle + \equiv$ for  $i \leftarrow 0$  to '37 do  $xchr[i] \leftarrow ??$ ; for  $i \leftarrow '177$  to '377 do  $xchr[i] \leftarrow ??$ ;

**15.** The following system-independent code makes the *xord* array contain a suitable inverse to the information in *xchr*.

 $\langle \text{Set initial values } 13 \rangle + \equiv$ for  $i \leftarrow first\_text\_char$  to  $last\_text\_char$  do  $xord[chr(i)] \leftarrow "\_";$ for  $i \leftarrow 1$  to '377 do  $xord[xchr[i]] \leftarrow i;$  $xord[`?`] \leftarrow "?";$  **16.** The *input\_ln* routine waits for the user to type a line at his or her terminal; then it puts ASCII-code equivalents for the characters on that line into the *buffer* array. The *term\_in* file is used for terminal input.

Since the terminal is being used for both input and output, some systems need a special routine to make sure that the user can see a prompt message before waiting for input based on that message. (Otherwise the message may just be sitting in a hidden buffer somewhere, and the user will have no idea what the program is waiting for.) We shall call a system-dependent subroutine *update\_terminal* in order to avoid this problem.

**define**  $update\_terminal \equiv break(output)$  { empty the terminal output buffer }

 $\langle \text{Globals in the outer block } 12 \rangle +\equiv$ buffer: **array** [0...terminal\_line\_length] **of** 0...255; term\_in: text\_file; { the terminal, considered as an input file }

17. A global variable *line\_length* records the first buffer position after the line just read.

procedure input\_ln; { inputs a line from the terminal }
 begin update\_terminal; reset(term\_in);
 if eoln(term\_in) then read\_ln(term\_in);
 line\_length ← 0;
 while (line\_length < terminal\_line\_length) ∧ ¬eoln(term\_in) do
 begin buffer[line\_length] ← xord[term\_in↑]; incr(line\_length); get(term\_in);
 end;
 end;</pre>

18. The global variable  $buf_ptr$  is used while scanning each line of input; it points to the first unread character in buffer.

 $\langle \text{Globals in the outer block } 12 \rangle +\equiv buf_ptr: 0.. terminal_line_length; { the number of characters read } line_length: 0.. terminal_line_length; { end of line read by input_ln }$ 

19. Device-independent file format. Before we get into the details of GFtoDVI, we need to know exactly what DVI files are. The form of such files was designed by David R. Fuchs in 1979. Almost any reasonable typesetting device can be driven by a program that takes DVI files as input, and dozens of such DVI-to-whatever programs have been written. Thus, it is possible to print the output of document compilers like T<sub>E</sub>X on many different kinds of equipment. (The following material has been copied almost verbatim from the program for T<sub>F</sub>X.)

A DVI file is a stream of 8-bit bytes, which may be regarded as a series of commands in a machine-like language. The first byte of each command is the operation code, and this code is followed by zero or more bytes that provide parameters to the command. The parameters themselves may consist of several consecutive bytes; for example, the '*set\_rule*' command has two parameters, each of which is four bytes long. Parameters are usually regarded as nonnegative integers; but four-byte-long parameters, and shorter parameters that denote distances, can be either positive or negative. Such parameters are given in two's complement notation. For example, a two-byte-long distance parameter has a value between  $-2^{15}$  and  $2^{15} - 1$ .

Incidentally, when two or more 8-bit bytes are combined to form an integer of 16 or more bits, the most significant bytes appear first in the file. This is called BigEndian order.

A DVI file consists of a "preamble," followed by a sequence of one or more "pages," followed by a "postamble." The preamble is simply a *pre* command, with its parameters that define the dimensions used in the file; this must come first. Each "page" consists of a *bop* command, followed by any number of other commands that tell where characters are to be placed on a physical page, followed by an *eop* command. The pages appear in the order that they were generated, not in any particular numerical order. If we ignore *nop* commands and *fnt\_def* commands (which are allowed between any two commands in the file), each *eop* command is immediately followed by a *bop* command, or by a *post* command; in the latter case, there are no more pages in the file, and the remaining bytes form the postamble. Further details about the postamble will be explained later.

Some parameters in DVI commands are "pointers." These are four-byte quantities that give the location number of some other byte in the file; the first byte is number 0, then comes number 1, and so on. For example, one of the parameters of a *bop* command points to the previous *bop*; this makes it feasible to read the pages in backwards order, in case the results are being directed to a device that stacks its output face up. Suppose the preamble of a DVI file occupies bytes 0 to 99. Now if the first page occupies bytes 100 to 999, say, and if the second page occupies bytes 1000 to 1999, then the *bop* that starts in byte 1000 points to 100 and the *bop* that starts in byte 2000 points to 1000. (The very first *bop*, i.e., the one that starts in byte 100, has a pointer of -1.)

**20.** The DVI format is intended to be both compact and easily interpreted by a machine. Compactness is achieved by making most of the information implicit instead of explicit. When a DVI-reading program reads the commands for a page, it keeps track of several quantities: (a) The current font f is an integer; this value is changed only by *fnt* and *fnt\_num* commands. (b) The current position on the page is given by two numbers called the horizontal and vertical coordinates, h and v. Both coordinates are zero at the upper left corner of the page; moving to the right corresponds to increasing the horizontal coordinate, and moving down corresponds to increasing the vertical coordinate. Thus, the coordinates are essentially Cartesian, except that vertical directions are flipped; the Cartesian version of (h, v) would be (h, -v). (c) The current spacing amounts are given by four numbers w, x, y, and z, where w and x are used for horizontal spacing and where y and z are used for vertical spacing. (d) There is a stack containing (h, v, w, x, y, z) values; the DVI commands *push* and *pop* are used to change the current level of operation. Note that the current font f is not pushed and popped; the stack contains only information about positioning.

The values of h, v, w, x, y, and z are signed integers having up to 32 bits, including the sign. Since they represent physical distances, there is a small unit of measurement such that increasing h by 1 means moving a certain tiny distance to the right. The actual unit of measurement is variable, as explained below.

**21.** Here is a list of all the commands that may appear in a DVI file. Each command is specified by its symbolic name (e.g., *bop*), its opcode byte (e.g., 139), and its parameters (if any). The parameters are followed by a bracketed number telling how many bytes they occupy; for example, 'p[4]' means that parameter p is four bytes long.

- $set\_char\_0$  0. Typeset character number 0 from font f such that the reference point of the character is at (h, v). Then increase h by the width of that character. Note that a character may have zero or negative width, so one cannot be sure that h will advance after this command; but h usually does increase.
- set\_char\_1 through set\_char\_127 (opcodes 1 to 127). Do the operations of set\_char\_0; but use the character whose number matches the opcode, instead of character 0.
- set1 128 c[1]. Same as set\_char\_0, except that character number c is typeset. TEX82 uses this command for characters in the range  $128 \le c < 256$ .
- set2 129 c[2]. Same as set1, except that c is two bytes long, so it is in the range  $0 \le c < 65536$ .
- set3 130 c[3]. Same as set1, except that c is three bytes long, so it can be as large as  $2^{24} 1$ . Not even the Chinese language has this many characters, but this command might prove useful in some yet unforeseen way.
- set 4131 c[4]. Same as set 1, except that c is four bytes long, possibly even negative. Imagine that.
- set\_rule 132 a[4] b[4]. Typeset a solid black rectangle of height a and width b, with its bottom left corner at (h, v). Then set  $h \leftarrow h + b$ . If either  $a \leq 0$  or  $b \leq 0$ , nothing should be typeset. Note that if b < 0, the value of h will decrease even though nothing else happens.
- put1 133 c[1]. Typeset character number c from font f such that the reference point of the character is at (h, v). (The 'put' commands are exactly like the 'set' commands, except that they simply put out a character or a rule without moving the reference point afterwards.)
- put2 134 c[2]. Same as set2, except that h is not changed.
- put 3135 c[3]. Same as set 3, except that h is not changed.
- put 4 136 c[4]. Same as set 4, except that h is not changed.
- put\_rule 137 a[4] b[4]. Same as set\_rule, except that h is not changed.
- *nop* 138. No operation, do nothing. Any number of *nop*'s may occur between DVI commands, but a *nop* cannot be inserted between a command and its parameters or between two parameters.
- bop 139  $c_0[4] c_1[4] \ldots c_9[4] p[4]$ . Beginning of a page: Set  $(h, v, w, x, y, z) \leftarrow (0, 0, 0, 0, 0, 0)$  and set the stack empty. Set the current font f to an undefined value. The ten  $c_i$  parameters can be used to identify pages, if a user wants to print only part of a DVI file; T<sub>E</sub>X82 gives them the values of \count0  $\ldots$  \count9 at the time \shipout was invoked for this page. The parameter p points to the previous bop command in the file, where the first bop has p = -1.
- eop 140. End of page: Print what you have read since the previous bop. At this point the stack should be empty. (The DVI-reading programs that drive most output devices will have kept a buffer of the material that appears on the page that has just ended. This material is largely, but not entirely, in order by v coordinate and (for fixed v) by h coordinate; so it usually needs to be sorted into some order that is appropriate for the device in question. GFtoDVI does not do such sorting.)
- push 141. Push the current values of (h, v, w, x, y, z) onto the top of the stack; do not change any of these values. Note that f is not pushed.
- pop 142. Pop the top six values off of the stack and assign them to (h, v, w, x, y, z). The number of pops should never exceed the number of pushes, since it would be highly embarrassing if the stack were empty at the time of a pop command.
- right 143 b[1]. Set  $h \leftarrow h + b$ , i.e., move right b units. The parameter is a signed number in two's complement notation,  $-128 \le b < 128$ ; if b < 0, the reference point actually moves left.
- right2 144 b[2]. Same as right1, except that b is a two-byte quantity in the range  $-32768 \le b < 32768$ .
- right 3 145 b[3]. Same as right 1, except that b is a three-byte quantity in the range  $-2^{23} \le b < 2^{23}$ .

*right*/4 146 *b*[4]. Same as *right*/1, except that *b* is a four-byte quantity in the range  $-2^{31} \le b < 2^{31}$ .

- w0 147. Set  $h \leftarrow h + w$ ; i.e., move right w units. With luck, this parameterless command will usually suffice, because the same kind of motion will occur several times in succession; the following commands explain how w gets particular values.
- w1 148 b[1]. Set  $w \leftarrow b$  and  $h \leftarrow h + b$ . The value of b is a signed quantity in two's complement notation, -128  $\leq b < 128$ . This command changes the current w spacing and moves right by b.
- w2 149 b[2]. Same as w1, but b is a two-byte-long parameter,  $-32768 \le b < 32768$ .
- w3 150 b[3]. Same as w1, but b is a three-byte-long parameter,  $-2^{23} \le b < 2^{23}$ .
- $w_{4}$  151 b[4]. Same as  $w_{1}$ , but b is a four-byte-long parameter,  $-2^{31} \leq b < 2^{31}$ .
- x0 152. Set  $h \leftarrow h + x$ ; i.e., move right x units. The 'x' commands are like the 'w' commands except that they involve x instead of w.
- x1 153 b[1]. Set  $x \leftarrow b$  and  $h \leftarrow h + b$ . The value of b is a signed quantity in two's complement notation, -128  $\leq b < 128$ . This command changes the current x spacing and moves right by b.
- x2 154 b[2]. Same as x1, but b is a two-byte-long parameter,  $-32768 \le b < 32768$ .
- x3 155 b[3]. Same as x1, but b is a three-byte-long parameter,  $-2^{23} \le b < 2^{23}$ .
- x4 156 b[4]. Same as x1, but b is a four-byte-long parameter,  $-2^{31} \le b < 2^{31}$ .
- down1 157 a[1]. Set  $v \leftarrow v + a$ , i.e., move down a units. The parameter is a signed number in two's complement notation,  $-128 \le a < 128$ ; if a < 0, the reference point actually moves up.
- down2 158 a[2]. Same as down1, except that a is a two-byte quantity in the range  $-32768 \le a < 32768$ .
- down3 159 a[3]. Same as down1, except that a is a three-byte quantity in the range  $-2^{23} \le a < 2^{23}$ .
- down4 160 a[4]. Same as down1, except that a is a four-byte quantity in the range  $-2^{31} \le a < 2^{31}$ .
- y0 161. Set  $v \leftarrow v + y$ ; i.e., move down y units. With luck, this parameterless command will usually suffice, because the same kind of motion will occur several times in succession; the following commands explain how y gets particular values.
- y1 162 a[1]. Set  $y \leftarrow a$  and  $v \leftarrow v + a$ . The value of a is a signed quantity in two's complement notation, -128  $\leq a < 128$ . This command changes the current y spacing and moves down by a.
- y2 163 a[2]. Same as y1, but a is a two-byte-long parameter,  $-32768 \le a < 32768$ .
- y3 164 a[3]. Same as y1, but a is a three-byte-long parameter,  $-2^{23} \le a < 2^{23}$ .
- y4 165 a[4]. Same as y1, but a is a four-byte-long parameter,  $-2^{31} \le a < 2^{31}$ .
- z0 166. Set  $v \leftarrow v + z$ ; i.e., move down z units. The 'z' commands are like the 'y' commands except that they involve z instead of y.
- z1 167 a[1]. Set  $z \leftarrow a$  and  $v \leftarrow v + a$ . The value of a is a signed quantity in two's complement notation, -128  $\leq a < 128$ . This command changes the current z spacing and moves down by a.
- z2 168 a[2]. Same as z1, but a is a two-byte-long parameter,  $-32768 \le a < 32768$ .
- z3 169 a[3]. Same as z1, but a is a three-byte-long parameter,  $-2^{23} \le a < 2^{23}$ .
- $z_4$  170 a[4]. Same as  $z_1$ , but a is a four-byte-long parameter,  $-2^{31} \le a < 2^{31}$ .
- $fnt_num_0$  171. Set  $f \leftarrow 0$ . Font 0 must previously have been defined by a  $fnt_def$  instruction, as explained below.
- $fnt_num_1$  through  $fnt_num_63$  (opcodes 172 to 234). Set  $f \leftarrow 1, \ldots, f \leftarrow 63$ , respectively.
- fnt1 235 k[1]. Set  $f \leftarrow k$ . T<sub>F</sub>X82 uses this command for font numbers in the range  $64 \le k < 256$ .
- fnt2 236 k[2]. Same as fnt1, except that k is two bytes long, so it is in the range  $0 \le k < 65536$ . TEX82 never generates this command, but large font numbers may prove useful for specifications of color or texture, or they may be used for special fonts that have fixed numbers in some external coding scheme.
- fnt3 237 k[3]. Same as fnt1, except that k is three bytes long, so it can be as large as  $2^{24} 1$ .

- fnt 238 k[4]. Same as fnt 1, except that k is four bytes long; this is for the really big font numbers (and for the negative ones).
- xxx1 239 k[1] x[k]. This command is undefined in general; it functions as a (k+2)-byte *nop* unless special DVI-reading programs are being used. TEX82 generates xxx1 when a short enough \special appears, setting k to the number of bytes being sent. It is recommended that x be a string having the form of a keyword followed by possible parameters relevant to that keyword.
- xxx2 240 k[2] x[k]. Like xxx1, but  $0 \le k < 65536$ .
- xxx3 241 k[3] x[k]. Like xxx1, but  $0 \le k < 2^{24}$ .
- xxx4 242 k[4] x[k]. Like xxx1, but k can be ridiculously large. T<sub>E</sub>X82 uses xxx4 when xxx1 would be incorrect.
- fnt\_def1 243 k[1] c[4] s[4] d[4] a[1] l[1] n[a+l]. Define font k, where  $0 \le k < 256$ ; font definitions will be explained shortly.
- fnt\_def2 244 k[2] c[4] s[4] d[4] a[1] l[1] n[a + l]. Define font k, where  $0 \le k < 65536$ .
- fnt\_def3 245 k[3] c[4] s[4] d[4] a[1] l[1] n[a + l]. Define font k, where  $0 \le k < 2^{24}$ .
- fnt\_def4 246 k[4] c[4] s[4] d[4] a[1] l[1] n[a+l]. Define font k, where  $-2^{31} \le k < 2^{31}$ .
- pre 247 i[1] num[4] den[4] mag[4] k[1] x[k]. Beginning of the preamble; this must come at the very beginning of the file. Parameters i, num, den, mag, k, and x are explained below.

post 248. Beginning of the postamble, see below.

post\_post 249. Ending of the postamble, see below.

Commands 250–255 are undefined at the present time.

22. Only a few of the operation codes above are actually needed by GFtoDVI.

```
define set1 = 128
                    { typeset a character and move right }
define put\_rule = 137 { typeset a rule }
define bop = 139
                   { beginning of page }
define eop = 140  { ending of page }
define push = 141 { save the current positions }
define pop = 142 { restore previous positions }
define right_4 = 146 \{ move right \}
define down_4 = 160 \{ move down \}
define z\theta = 166 \{ \text{move down } z \}
define z_4 = 170 \{ \text{move down and set } z \}
define fnt_num_0 = 171 { set current font to 0 }
define fnt\_def1 = 243 { define the meaning of a font number }
define pre = 247 \{ \text{preamble} \}
define post = 248 { postamble beginning }
define post_post = 249 { postamble ending }
```

**23.** The preamble contains basic information about the file as a whole. As stated above, there are six parameters:

The *i* byte identifies DVI format; currently this byte is always set to 2. (The value i = 3 is currently used for an extended format that allows a mixture of right-to-left and left-to-right typesetting. Some day we will set i = 4, when DVI format makes another incompatible change—perhaps in the year 2048.)

The next two parameters, num and den, are positive integers that define the units of measurement; they are the numerator and denominator of a fraction by which all dimensions in the DVI file could be multiplied in order to get lengths in units of  $10^{-7}$  meters. (For example, there are exactly 7227 T<sub>E</sub>X points in 254 centimeters, and T<sub>E</sub>X82 works with scaled points where there are  $2^{16}$  sp in a point, so T<sub>E</sub>X82 sets num = 25400000 and den = 7227  $\cdot 2^{16} = 473628672$ .)

The mag parameter is what  $T_EX82$  calls mag, i.e., 1000 times the desired magnification. The actual fraction by which dimensions are multiplied is therefore  $mag \cdot num/1000 den$ . Note that if a  $T_EX$  source document does not call for any 'true' dimensions, and if you change it only by specifying a different mag setting, the DVI file that  $T_EX$  creates will be completely unchanged except for the value of mag in the preamble and postamble. (Fancy DVI-reading programs allow users to override the mag setting when a DVI file is being printed.)

Finally, k and x allow the DVI writer to include a comment, which is not interpreted further. The length of comment x is k, where  $0 \le k < 256$ .

**define**  $dvi_id_byte = 2$  {identifies the kind of DVI files described here}

## **24.** Font definitions for a given font number k contain further parameters

$$c[4] \ s[4] \ d[4] \ a[1] \ l[1] \ n[a+l].$$

The four-byte value c is the check sum that  $T_{E}X$  (or whatever program generated the DVI file) found in the TFM file for this font; c should match the check sum of the font found by programs that read this DVI file.

Parameter s contains a fixed-point scale factor that is applied to the character widths in font k; font dimensions in TFM files and other font files are relative to this quantity, which is always positive and less than  $2^{27}$ . It is given in the same units as the other dimensions of the DVI file. Parameter d is similar to s; it is the "design size," and (like s) it is given in DVI units. Thus, font k is to be used at  $mag \cdot s/1000d$  times its normal size.

The remaining part of a font definition gives the external name of the font, which is an ASCII string of length a + l. The number a is the length of the "area" or directory, and l is the length of the font name itself; the standard local system font area is supposed to be used when a = 0. The n field contains the area in its first a bytes.

Font definitions must appear before the first use of a particular font number. Once font k is defined, it must not be defined again; however, we shall see below that font definitions appear in the postamble as well as in the pages, so in this sense each font number is defined exactly twice, if at all. Like *nop* commands, font definitions can appear before the first *bop*, or between an *eop* and a *bop*.

25. The last page in a DVI file is followed by '*post*'; this command introduces the postamble, which summarizes important facts that  $T_EX$  has accumulated about the file, making it possible to print subsets of the data with reasonable efficiency. The postamble has the form

 $\begin{array}{l} post \ p[4] \ num[4] \ den[4] \ mag[4] \ l[4] \ u[4] \ s[2] \ t[2] \\ \langle \ font \ definitions \, \rangle \\ post\_post \ q[4] \ i[1] \ 223's[\geq 4] \end{array}$ 

Here p is a pointer to the final *bop* in the file. The next three parameters, *num*, *den*, and *mag*, are duplicates of the quantities that appeared in the preamble.

Parameters l and u give respectively the height-plus-depth of the tallest page and the width of the widest page, in the same units as other dimensions of the file. These numbers might be used by a DVI-reading program to position individual "pages" on large sheets of film or paper; however, the standard convention for output on normal size paper is to position each page so that the upper left-hand corner is exactly one inch from the left and the top. Experience has shown that it is unwise to design DVI-to-printer software that attempts cleverly to center the output; a fixed position of the upper left corner is easiest for users to understand and to work with. Therefore l and u are often ignored.

Parameter s is the maximum stack depth (i.e., the largest excess of *push* commands over *pop* commands) needed to process this file. Then comes t, the total number of pages (*bop* commands) present.

The postamble continues with font definitions, which are any number of  $fnt_def$  commands as described above, possibly interspersed with *nop* commands. Each font number that is used in the DVI file must be defined exactly twice: Once before it is first selected by a *fnt* command, and once in the postamble.

**26.** The last part of the postamble, following the *post\_post* byte that signifies the end of the font definitions, contains q, a pointer to the *post* command that started the postamble. An identification byte, i, comes next; this currently equals 2, as in the preamble.

The *i* byte is followed by four or more bytes that are all equal to the decimal number 223 (i.e., '337 in octal). T<sub>E</sub>X puts out four to seven of these trailing bytes, until the total length of the file is a multiple of four bytes, since this works out best on machines that pack four bytes per word; but any number of 223's is allowed, as long as there are at least four of them. In effect, 223 is a sort of signature that is added at the very end.

This curious way to finish off a DVI file makes it feasible for DVI-reading programs to find the postamble first, on most computers, even though  $T_EX$  wants to write the postamble last. Most operating systems permit random access to individual words or bytes of a file, so the DVI reader can start at the end and skip backwards over the 223's until finding the identification byte. Then it can back up four bytes, read q, and move to byte q of the file. This byte should, of course, contain the value 248 (*post*); now the postamble can be read, so the DVI reader can discover all the information needed for typesetting the pages. Note that it is also possible to skip through the DVI file at reasonably high speed to locate a particular page, if that proves desirable. This saves a lot of time, since DVI files used in production jobs tend to be large.

Unfortunately, however, standard Pascal does not include the ability to access a random position in a file, or even to determine the length of a file. Almost all systems nowadays provide the necessary capabilities, so DVI format has been designed to work most efficiently with modern operating systems.

27. Generic font file format. The "generic font" (GF) input files that GFtoDVI must deal with have a structure that was inspired by DVI format, although the operation codes are quite different in most cases. The term *generic* indicates that this file format doesn't match the conventions of any name-brand manufacturer; but it is easy to convert GF files to the special format required by almost all digital phototypesetting equipment. There's a strong analogy between the DVI files written by T<sub>E</sub>X and the GF files written by METAFONT; and, in fact, the reader will notice that many of the paragraphs below are identical to their counterparts in the description of DVI already given. The following description has been lifted almost verbatim from the program for METAFONT.

A GF file is a stream of 8-bit bytes that may be regarded as a series of commands in a machine-like language. The first byte of each command is the operation code, and this code is followed by zero or more bytes that provide parameters to the command. The parameters themselves may consist of several consecutive bytes; for example, the 'boc' (beginning of character) command has six parameters, each of which is four bytes long. Parameters are usually regarded as nonnegative integers; but four-byte-long parameters can be either positive or negative, hence they range in value from  $-2^{31}$  to  $2^{31} - 1$ . As in DVI files, numbers that occupy more than one byte position appear in BigEndian order, and negative numbers appear in two's complement notation.

A GF file consists of a "preamble," followed by a sequence of one or more "characters," followed by a "postamble." The preamble is simply a *pre* command, with its parameters that introduce the file; this must come first. Each "character" consists of a *boc* command, followed by any number of other commands that specify "black" pixels, followed by an *eoc* command. The characters appear in the order that METAFONT generated them. If we ignore no-op commands (which are allowed between any two commands in the file), each *eoc* command is immediately followed by a *boc* command, or by a *post* command; in the latter case, there are no more characters in the file, and the remaining bytes form the postamble. Further details about the postamble will be explained later.

Some parameters in GF commands are "pointers." These are four-byte quantities that give the location number of some other byte in the file; the first file byte is number 0, then comes number 1, and so on.

**28.** The GF format is intended to be both compact and easily interpreted by a machine. Compactness is achieved by making most of the information relative instead of absolute. When a GF-reading program reads the commands for a character, it keeps track of two quantities: (a) the current column number, m; and (b) the current row number, n. These are 32-bit signed integers, although most actual font formats produced from GF files will need to curtail this vast range because of practical limitations. (METAFONT output will never allow |m| or |n| to get extremely large, but the GF format tries to be more general.)

How do GF's row and column numbers correspond to the conventions of TEX and METAFONT? Well, the "reference point" of a character, in TEX's view, is considered to be at the lower left corner of the pixel in row 0 and column 0. This point is the intersection of the baseline with the left edge of the type; it corresponds to location (0,0) in METAFONT programs. Thus the pixel in GF row 0 and column 0 is METAFONT's unit square, comprising the region of the plane whose coordinates both lie between 0 and 1. The pixel in GF row n and column m consists of the points whose METAFONT coordinates (x, y) satisfy  $m \le x \le m + 1$  and  $n \le y \le n + 1$ . Negative values of m and x correspond to columns of pixels left of the reference point; negative values of n and y correspond to rows of pixels below the baseline.

Besides m and n, there's also a third aspect of the current state, namely the *paint\_switch*, which is always either *black* or *white*. Each *paint* command advances m by a specified amount d, and blackens the intervening pixels if *paint\_switch* = *black*; then the *paint\_switch* changes to the opposite state. GF's commands are designed so that m will never decrease within a row, and n will never increase within a character; hence there is no way to whiten a pixel that has been blackened. **29.** Here is a list of all the commands that may appear in a GF file. Each command is specified by its symbolic name (e.g., *boc*), its opcode byte (e.g., 67), and its parameters (if any). The parameters are followed by a bracketed number telling how many bytes they occupy; for example, 'd[2]' means that parameter d is two bytes long.

- $paint_0 0$ . This is a paint command with d = 0; it does nothing but change the paint\_switch from black to white or vice versa.
- paint\_1 through paint\_63 (opcodes 1 to 63). These are paint commands with d = 1 to 63, defined as follows: If paint\_switch = black, blacken d pixels of the current row n, in columns m through m + d - 1 inclusive. Then, in any case, complement the paint\_switch and advance m by d.
- paint1 64 d[1]. This is a paint command with a specified value of d; METAFONT uses it to paint when  $64 \le d < 256$ .
- paint2 65 d[2]. Same as paint1, but d can be as high as 65535.
- paint3 66 d[3]. Same as paint1, but d can be as high as  $2^{24} 1$ . METAFONT never needs this command, and it is hard to imagine anybody making practical use of it; surely a more compact encoding will be desirable when characters can be this large. But the command is there, anyway, just in case.
- boc 67 c[4] p[4]  $min_m$ [4]  $max_m$ [4]  $min_n$ [4]  $max_n$ [4]. Beginning of a character: Here c is the character code, and p points to the previous character beginning (if any) for characters having this code number modulo 256. (The pointer p is -1 if there was no prior character with an equivalent code.) The values of registers m and n defined by the instructions that follow for this character must satisfy  $min_m \leq m \leq max_m$  and  $min_n \leq n \leq max_n$ . (The values of  $max_m$  and  $min_n$  need not be the tightest bounds possible.) When a GF-reading program sees a boc, it can use  $min_m$ ,  $max_m$ ,  $min_n$ , and  $max_n$  to initialize the bounds of an array. Then it sets  $m \leftarrow min_m$ ,  $n \leftarrow max_n$ , and  $paint_switch \leftarrow white$ .
- boc1 68 c[1]  $del_m[1]$   $max_m[1]$   $del_n[1]$   $max_n[1]$ . Same as boc, but p is assumed to be -1; also  $del_m = max_m min_m$  and  $del_n = max_n min_n$  are given instead of  $min_m$  and  $min_n$ . The one-byte parameters must be between 0 and 255, inclusive. (This abbreviated *boc* saves 19 bytes per character, in common cases.)
- eoc 69. End of character: All pixels blackened so far constitute the pattern for this character. In particular, a completely blank character might have eoc immediately following boc.
- skip0 70. Decrease n by 1 and set  $m \leftarrow min_m$ ,  $paint_switch \leftarrow white$ . (This finishes one row and begins another, ready to whiten the leftmost pixel in the new row.)
- skip1 71 d[1]. Decrease n by d + 1, set  $m \leftarrow min_m$ , and set paint\_switch  $\leftarrow$  white. This is a way to produce d all-white rows.
- skip2 72 d[2]. Same as skip1, but d can be as large as 65535.
- skip3 73 d[3]. Same as skip1, but d can be as large as  $2^{24} 1$ . METAFONT obviously never needs this command.
- *new\_row\_0* 74. Decrease n by 1 and set  $m \leftarrow min_m$ , *paint\_switch*  $\leftarrow$  *black*. (This finishes one row and begins another, ready to *blacken* the leftmost pixel in the new row.)
- *new\_row\_1* through *new\_row\_164* (opcodes 75 to 238). Same as *new\_row\_0*, but with  $m \leftarrow min_m + 1$  through  $min_m + 164$ , respectively.
- xxx1 239 k[1] x[k]. This command is undefined in general; it functions as a (k + 2)-byte  $no_op$  unless special GF-reading programs are being used. METAFONT generates xxx commands when encountering a **special** string; this occurs in the GF file only between characters, after the preamble, and before the postamble. However, xxx commands might appear within characters, in GF files generated by other processors. It is recommended that x be a string having the form of a keyword followed by possible parameters relevant to that keyword.
- *xxx2* 240 k[2] x[k]. Like *xxx1*, but  $0 \le k < 65536$ .
- xxx3 241 k[3] x[k]. Like xxx1, but  $0 \le k < 2^{24}$ . METAFONT uses this when sending a special string whose length exceeds 255.

xxx4 242 k[4] x[k]. Like xxx1, but k can be ridiculously large; k mustn't be negative.

- yyy 243 y[4]. This command is undefined in general; it functions as a 5-byte  $no_op$  unless special GF-reading programs are being used. METAFONT puts *scaled* numbers into yyy's, as a result of **numspecial** commands; the intent is to provide numeric parameters to xxx commands that immediately precede.
- *no\_op* 244. No operation, do nothing. Any number of *no\_op*'s may occur between **GF** commands, but a *no\_op* cannot be inserted between a command and its parameters or between two parameters.
- char\_loc 245 c[1] dx[4] dy[4] w[4] p[4]. This command will appear only in the postamble, which will be explained shortly.
- char\_loc0 246 c[1] dm[1] w[4] p[4]. Same as char\_loc, except that dy is assumed to be zero, and the value of dx is taken to be 65536 \* dm, where  $0 \le dm < 256$ .
- pre 247 i[1] k[1] x[k]. Beginning of the preamble; this must come at the very beginning of the file. Parameter i is an identifying number for GF format, currently 131. The other information is merely commentary; it is not given special interpretation like xxx commands are. (Note that xxx commands may immediately follow the preamble, before the first *boc*.)
- post 248. Beginning of the postamble, see below.

post\_post 249. Ending of the postamble, see below.

Commands 250–255 are undefined at the present time.

**define**  $gf_id_byte = 131$  {identifies the kind of GF files described here }

**30.** Here are the opcodes that **GFtoDVI** actually refers to.

{ beginning of the *paint* commands } define  $paint_0 = 0$ { move right a given number of columns, then black  $\leftrightarrow$  white } define paint1 = 64{ ditto, with potentially larger number of columns } define paint2 = 65{ ditto, with potentially excessive number of columns } define paint3 = 66**define** boc = 67 { beginning of a character } **define** boc1 = 68 { abbreviated boc } **define** eoc = 69 { end of a character } **define**  $skip\theta = 70$  { skip no blank rows } define skip1 = 71{ skip over blank rows } define skip2 = 72{ skip over lots of blank rows } define skip3 = 73{ skip over a huge number of blank rows } **define**  $new_row_0 = 74$  { move down one row and then right } define xxx1 = 239{ for **special** strings } define xxx2 = 240{ for somewhat long **special** strings } { for extremely long **special** strings } define xxx3 = 241define xxx4 = 242{ for incredibly long **special** strings } define yyy = 243 { for numspecial numbers } define  $no_{-}op = 244 \{ no operation \}$ 

**31.** The last character in a **GF** file is followed by '*post*'; this command introduces the postamble, which summarizes important facts that METAFONT has accumulated. The postamble has the form

post p[4] ds[4] cs[4] hppp[4] vppp[4] min\_m[4] max\_m[4] min\_n[4] max\_n[4] (character locators ) post\_post q[4] i[1] 223's[ $\geq$ 4]

Here p is a pointer to the byte following the final *eoc* in the file (or to the byte following the preamble, if there are no characters); it can be used to locate the beginning of xxx commands that might have preceded the postamble. The ds and cs parameters give the design size and check sum, respectively, of the font (see the description of TFM format below). Parameters hppp and vppp are the ratios of pixels per point, horizontally and vertically, expressed as scaled integers (i.e., multiplied by  $2^{16}$ ); they can be used to correlate the font with specific device resolutions, magnifications, and "at sizes." Then come min\_m, max\_m, min\_n, and max\_n, which bound the values that registers m and n assume in all characters in this GF file. (These bounds need not be the best possible; max\_m and min\_n may, on the other hand, be tighter than the similar bounds in boc commands. For example, some character may have  $min_n = -100$  in its boc, but it might turn out that n never gets lower than -50 in any character; then  $min_n$  can have any value  $\leq -50$ . If there are no characters in the file, it's possible to have  $min_m > max_m$  and/or  $min_n > max_n$ .)

**32.** Character locators are introduced by  $char\_loc$  commands, which specify a character residue c, character escapements (dx, dy), a character width w, and a pointer p to the beginning of that character. (If two or more characters have the same code c modulo 256, only the last will be indicated; the others can be located by following backpointers. Characters whose codes differ by a multiple of 256 are assumed to share the same font metric information, hence the TFM file contains only residues of character codes modulo 256. This convention is intended for oriental languages, when there are many character shapes but few distinct widths.)

The character escapements (dx, dy) are the values of METAFONT's **chardx** and **chardy** parameters; they are in units of *scaled* pixels; i.e., dx is in horizontal pixel units times  $2^{16}$ , and dy is in vertical pixel units times  $2^{16}$ . This is the intended amount of displacement after typesetting the character; for DVI files, dy should be zero, but other document file formats allow nonzero vertical escapement.

The character width w duplicates the information in the TFM file; it is  $2^{20}$  times the ratio of the true width to the font's design size.

The backpointer p points to the character's *boc*, or to the first of a sequence of consecutive *xxx* or *yyy* or *no\_op* commands that immediately precede the *boc*, if such commands exist; such "special" commands essentially belong to the characters, while the special commands after the final character belong to the postamble (i.e., to the font as a whole). This convention about p applies also to the backpointers in *boc* commands, even though it wasn't explained in the description of *boc*.

Pointer p might be -1 if the character exists in the TFM file but not in the GF file. This unusual situation can arise in METAFONT output if the user had proofing < 0 when the character was being shipped out, but then made proofing  $\geq 0$  in order to get a GF file.

**33.** The last part of the postamble, following the *post\_post* byte that signifies the end of the character locators, contains q, a pointer to the *post* command that started the postamble. An identification byte, i, comes next; this currently equals 131, as in the preamble.

The *i* byte is followed by four or more bytes that are all equal to the decimal number 223 (i.e., '337 in octal). METAFONT puts out four to seven of these trailing bytes, until the total length of the file is a multiple of four bytes, since this works out best on machines that pack four bytes per word; but any number of 223's is allowed, as long as there are at least four of them. In effect, 223 is a sort of signature that is added at the very end.

This curious way to finish off a GF file makes it feasible for GF-reading programs to find the postamble first, on most computers, even though METAFONT wants to write the postamble last. Most operating systems permit random access to individual words or bytes of a file, so the GF reader can start at the end and skip backwards over the 223's until finding the identification byte. Then it can back up four bytes, read q, and move to byte q of the file. This byte should, of course, contain the value 248 (*post*); now the postamble can be read, so the GF reader can discover all the information needed for individual characters.

Unfortunately, however, standard Pascal does not include the ability to access a random position in a file, or even to determine the length of a file. Almost all systems nowadays provide the necessary capabilities, so GF format has been designed to work most efficiently with modern operating systems. But if GF files have to be processed under the restrictions of standard Pascal, one can simply read them from front to back. This will be adequate for most applications. However, the postamble-first approach would facilitate a program that merges two GF files, replacing data from one that is overridden by corresponding data in the other.

**34.** Extensions to the generic format. The *xxx* and *yyy* instructions understood by GFtoDVI will be listed now, so that we have a convenient reference to all of the special assumptions made later.

Each special instruction begins with an xxx command, which consists of either a keyword by itself, or a keyword followed by a space followed by arguments. This xxx command may then be followed by yyy commands that are understood to be arguments.

The keywords of special instructions that are intended to be used at many different sites should be published as widely as possible in order to minimize conflicts. The first person to establish a keyword presumably has a right to define it; GFtoDVI, as the first program to use extended GF commands, has the opportunity of choosing any keywords it likes, and the responsibility of choosing reasonable ones. Since labels are expected to account for the bulk of extended commands in typical uses of METAFONT, the "null" keyword has been set aside to denote a labeling command.

- 35. Here then are the special commands of GFtoDVI.
  - $\lfloor n \langle \text{string} \rangle x y$ . Here n denotes the type of label; the characters 1, 2, 3, 4 respectively denote labels forced to be at the top, left, right, or bottom of their dot, and the characters 5, 6, 7, 8 stand for the same possibilities but with no dot printed. The character 0 instructs GFtoDVI to choose one of the first four possibilities, if there's no overlap with other labels or dots, otherwise an "overflow" entry is placed at the right of the figure. The character / is the same as 0 except that overflow entries are not produced. The label itself is the  $\langle \text{string} \rangle$  that follows. METAFONT coordinates of the point that is to receive this label are given by arguments x and y, in units of scaled pixels. (These arguments appear in yyy commands.) (Precise definitions of the size and positioning of labels, and of the notion of "conflicting" labels, will be given later.)
  - rule  $x_1 y_1 x_2 y_2$ . This command draws a line from  $(x_1, y_1)$  to  $(x_2, y_2)$  in METAFONT coordinates. The present implementation does this only if the line is either horizontal or vertical, or if its slope matches the slope of the slant font.
  - title<sub>L</sub>(string). This command (which is output by METAFONT when it sees a "title statement") specifies a string that will appear at the top of the next proofsheet to be output by GFtoDVI. If more than one title is given, they will appear in sequence; titles should be short enough to fit on a single line.
  - titlefontu(string). This command, and the other font-naming commands below, must precede the first boc in the GF file. It overrides the current font used to typeset the titles at the top of proofsheets. GFtoDVI has default fonts that will be used if none other are specified; the "current" title font is initially the default title font.
  - titlefontarea<sub>u</sub>(string). This command overrides the current file area (or directory name) from which GFtoDVI will try to find metric information for the title font.
  - titlefontat s. This command overrides the current "at size" that will be used for the title font. (See the discussion of font metric files below, for the meaning of "at size" versus "design size.") The value of s is given in units of scaled points.
  - labelfontu(string). This command overrides the current font used to typeset the labels that are superimposed on proof figures. (The label font is fairly arbitrary, but it should be dark enough to stand out when superimposed on gray pixels, and it should contain at least the decimal digits and the characters '(', ')', '=', '+', '-', ',', and '.'.)
  - labelfontarea⊔(string). This command overrides the current file area (or directory name) from which GFtoDVI will try to find metric information for the label font.
  - labelfontat s. This command overrides the current "at size" that will be used for the label font.
  - $grayfont_{\sqcup} \langle string \rangle$ . This command overrides the current font used to typeset the black pixels and the dots for labels. (Gray fonts will be explained in detail later.)
  - grayfontarea<sub>⊔</sub>(string). This command overrides the current file area (or directory name) from which GFtoDVI will try to find metric information for the gray font.
  - grayfontat s. This command overrides the current "at size" that will be used for the gray font.

- slantfont<sub>□</sub>(string). This command overrides the current font used to typeset rules that are neither horizontal nor vertical. (Slant fonts will be explained in detail later.)
- slantfontarea<sub>u</sub>(string). This command overrides the current file area (or directory name) from which GFtoDVI will try to find metric information for the slant font.
- slantfontat s. This command overrides the current "at size" that will be used for the slant font.
- rulethickness t. This command overrides the current value used for the thickness of rules. If the current value is negative, no rule will be drawn; if the current value is zero, the rule thickness will be specified by a parameter of the gray font. Each rule command uses the rule thickness that is current at the time the command appears; hence it is possible to get different thicknesses of rules on the same figure. The value of t is given in units of scaled points (T<sub>E</sub>X's 'sp'). At the beginning of each character the current rule thickness is zero.
- offset x y. This command overrides the current offset values that are added to all coordinates of a character being output; x and y are given as scaled METAFONT coordinates. This simply has the effect of repositioning the figures on the pages; the title line always appears in the same place, but the figure can be moved up, down, left, or right. At the beginning of each character the current offsets are zero.
- **xoffset** x. This command is output by METAFONT just before shipping out a character whose x offset is nonzero. GFtoDVI adds the specified amount to the x coordinates of all dots, labels, and rules in the following character.
- yoffset y. This command is output by METAFONT just before shipping out a character whose y offset is nonzero. GFtoDVI adds the specified amount to the y coordinates of all dots, labels, and rules in the following character.

**36.** Font metric data. Before we can get into the meaty details of GFtoDVI, we need to deal with yet another esoteric binary file format, since GFtoDVI also does elementary typesetting operations. Therefore it has to read important information about the fonts it will be using. The following material (again copied almost verbatim from  $T_FX$ ) describes the contents of so-called  $T_FX$  font metric (TFM) files.

The idea behind TFM files is that typesetting routines need a compact way to store the relevant information about fonts, and computer centers need a compact way to store the relevant information about several hundred fonts. TFM files are compact, and most of the information they contain is highly relevant, so they provide a solution to the problem. GFtoDVI uses only four fonts, but interesting changes in its output will occur when those fonts are varied.

The information in a TFM file appears in a sequence of 8-bit bytes. Since the number of bytes is always a multiple of 4, we could also regard the file as a sequence of 32-bit words; but  $T_EX$  uses the byte interpretation, and so does GFtoDVI. The individual bytes are considered to be unsigned numbers.

**37.** The first 24 bytes (6 words) of a TFM file contain twelve 16-bit integers that give the lengths of the various subsequent portions of the file. These twelve integers are, in order:

$$\begin{split} lf &= \text{length of the entire file, in words;} \\ lh &= \text{length of the header data, in words;} \\ bc &= \text{smallest character code in the font;} \\ ec &= \text{largest character code in the font;} \\ nw &= \text{number of words in the width table;} \\ nh &= \text{number of words in the height table;} \\ nd &= \text{number of words in the depth table;} \\ ni &= \text{number of words in the italic correction table;} \\ nl &= \text{number of words in the lig/kern table;} \\ nk &= \text{number of words in the kern table;} \\ ne &= \text{number of words in the extensible character table;} \\ np &= \text{number of font parameter words.} \end{split}$$

They are all nonnegative and less than  $2^{15}$ . We must have  $bc - 1 \le ec \le 255$ , and

$$lf = 6 + lh + (ec - bc + 1) + nw + nh + nd + ni + nl + nk + ne + np.$$

Note that a font may contain as many as 256 characters (if bc = 0 and ec = 255), and as few as 0 characters (if bc = ec + 1). When two or more 8-bit bytes are combined to form an integer of 16 or more bits, the bytes appear in BigEndian order.

 $\langle \text{Globals in the outer block } 12 \rangle + \equiv$ lf, lh, bc, ec, nw, nh, nd, ni, nl, nk, ne, np: 0... '777777; { subfile sizes } **38.** The rest of the TFM file may be regarded as a sequence of ten data arrays having the informal specification

 $\begin{array}{l} header: \mathbf{array} \ [0 \ .. \ lh - 1] \ \mathbf{of} \ stuff\\ char\_info: \mathbf{array} \ [bc \ .. \ ec] \ \mathbf{of} \ char\_info\_word\\ width: \mathbf{array} \ [0 \ .. \ nw - 1] \ \mathbf{of} \ fix\_word\\ height: \mathbf{array} \ [0 \ .. \ nh - 1] \ \mathbf{of} \ fix\_word\\ depth: \mathbf{array} \ [0 \ .. \ nd - 1] \ \mathbf{of} \ fix\_word\\ italic: \mathbf{array} \ [0 \ .. \ ni - 1] \ \mathbf{of} \ fix\_word\\ lig\_kern: \mathbf{array} \ [0 \ .. \ nk - 1] \ \mathbf{of} \ fix\_word\\ kern: \mathbf{array} \ [0 \ .. \ nk - 1] \ \mathbf{of} \ fix\_word\\ exten: \mathbf{array} \ [0 \ .. \ ne - 1] \ \mathbf{of} \ fix\_word\\ exten: \mathbf{array} \ [0 \ .. \ ne - 1] \ \mathbf{of} \ fix\_word\\ exten: \mathbf{array} \ [1 \ .. \ np] \ \mathbf{of} \ fix\_word\\ \end{array}$ 

The most important data type used here is a *fix\_word*, which is a 32-bit representation of a binary fraction. A *fix\_word* is a signed quantity, with the two's complement of the entire word used to represent negation. Of the 32 bits in a *fix\_word*, exactly 12 are to the left of the binary point; thus, the largest *fix\_word* value is  $2048 - 2^{-20}$ , and the smallest is -2048. We will see below, however, that all but two of the *fix\_word* values must lie between -16 and +16.

**39.** The first data array is a block of header information, which contains general facts about the font. The header must contain at least two words, and for TFM files to be used with Xerox printing software it must contain at least 18 words, allocated as described below. When different kinds of devices need to be interfaced, it may be necessary to add further words to the header block.

- header [0] is a 32-bit check sum that GFtoDVI will copy into the DVI output file whenever it uses the font. Later on when the DVI file is printed, possibly on another computer, the actual font that gets used is supposed to have a check sum that agrees with the one in the TFM file used by GFtoDVI. In this way, users will be warned about potential incompatibilities. (However, if the check sum is zero in either the font file or the TFM file, no check is made.) The actual relation between this check sum and the rest of the TFM file is not important; the check sum is simply an identification number with the property that incompatible fonts almost always have distinct check sums.
- header [1] is a fix\_word containing the design size of the font, in units of TEX points (7227 TEX points = 254 cm). This number must be at least 1.0; it is fairly arbitrary, but usually the design size is 10.0 for a "10 point" font, i.e., a font that was designed to look best at a 10-point size, whatever that really means. When a TEX user asks for a font 'at  $\delta$  pt', the effect is to override the design size and replace it by  $\delta$ , and to multiply the x and y coordinates of the points in the font image by a factor of  $\delta$  divided by the design size. Similarly, specific sizes can be substituted for the design size by GFtoDVI commands like 'titlefontat'. All other dimensions in the TFM file are fix\_word numbers in design-size units. Thus, for example, the value of param[6], one em or \quad, is often the fix\_word value  $2^{20} = 1.0$ , since many fonts have a design size equal to one em. The other dimensions must be less than 16 design-size units in absolute value; thus, header[1] and param[1] are the only fix\_word entries in the whole TFM file whose first byte might be something besides 0 or 255.
- header[2 .. 11], if present, contains 40 bytes that identify the character coding scheme. The first byte, which must be between 0 and 39, is the number of subsequent ASCII bytes actually relevant in this string, which is intended to specify what character-code-to-symbol convention is present in the font. Examples are ASCII for standard ASCII, TeX text for fonts like cmr10 and cmt19, TeX math extension for cmex10, XEROX text for Xerox fonts, GRAPHIC for special-purpose non-alphabetic fonts, GFGRAY for GFtoDVI's gray fonts, GFSLANT for GFtoDVI's slant fonts, UNSPECIFIED for the default case when there is no information. Parentheses should not appear in this name. (Such a string is said to be in BCPL format.)
- header[12...whatever] might also be present.

**40.** Next comes the *char\_info* array, which contains one *char\_info\_word* per character. Each *char\_info\_word* contains six fields packed into four bytes as follows.

first byte: width\_index (8 bits) second byte: height\_index (4 bits) times 16, plus depth\_index (4 bits) third byte: italic\_index (6 bits) times 4, plus tag (2 bits) fourth byte: remainder (8 bits)

The actual width of a character is  $width[width\_index]$ , in design-size units; this is a device for compressing information, since many characters have the same width. Since it is quite common for many characters to have the same height, depth, or italic correction, the TFM format imposes a limit of 16 different heights, 16 different depths, and 64 different italic corrections.

Incidentally, the relation width[0] = height[0] = depth[0] = italic[0] = 0 should always hold, so that an index of zero implies a value of zero. The width\_index should never be zero unless the character does not exist in the font, since a character is valid if and only if it lies between bc and ec and has a nonzero width\_index.

41. The tag field in a char\_info\_word has four values that explain how to interpret the remainder field.

tag = 0 (no\_tag) means that remainder is unused.

- tag = 1 ( $lig_tag$ ) means that this character has a ligature/kerning program starting at  $lig_kern[remainder]$ .
- tag = 2 (*list\_tag*) means that this character is part of a chain of characters of ascending sizes, and not the largest in the chain. The *remainder* field gives the character code of the next larger character.
- $tag = 3 \ (ext\_tag)$  means that this character code represents an extensible character, i.e., a character that is built up of smaller pieces so that it can be made arbitrarily large. The pieces are specified in exten[remainder].

**define**  $no_{tag} = 0$  { vanilla character }

**define**  $lig_tag = 1$  { character has a ligature/kerning program }

**define**  $list_tag = 2$  { character has a successor in a charlist }

**define**  $ext_tag = 3$  { character is extensible }

**42.** The *lig\_kern* array contains instructions in a simple programming language that explains what to do for special letter pairs. Each word in this array is a *lig\_kern\_command* of four bytes.

first byte: *skip\_byte*, indicates that this is the final program step if the byte is 128 or more, otherwise the next step is obtained by skipping this number of intervening steps.

second byte: *next\_char*, "if *next\_char* follows the current character, then perform the operation and stop, otherwise continue."

third byte: op\_byte, indicates a ligature step if less than 128, a kern step otherwise.

fourth byte: remainder.

In a kern step, an additional space equal to  $kern[256 * (op_byte - 128) + remainder]$  is inserted between the current character and *next\_char*. This amount is often negative, so that the characters are brought closer together by kerning; but it might be positive.

There are eight kinds of ligature steps, having  $op_byte$  codes 4a+2b+c where  $0 \le a \le b+c$  and  $0 \le b, c \le 1$ . The character whose code is *remainder* is inserted between the current character and *next\_char*; then the current character is deleted if b = 0, and *next\_char* is deleted if c = 0; then we pass over a characters to reach the next current character (which may have a ligature/kerning program of its own).

If the very first instruction of the  $lig\_kern$  array has  $skip\_byte = 255$ , the  $next\_char$  byte is the so-called right boundary character of this font; the value of  $next\_char$  need not lie between bc and ec. If the very last instruction of the  $lig\_kern$  array has  $skip\_byte = 255$ , there is a special ligature/kerning program for a left boundary character, beginning at location  $256 * op\_byte + remainder$ . The interpretation is that T<sub>E</sub>X puts implicit boundary characters before and after each consecutive string of characters from the same font. These implicit characters do not appear in the output, but they can affect ligatures and kerning.

If the very first instruction of a character's *lig\_kern* program has *skip\_byte* > 128, the program actually begins in location  $256 * op_byte + remainder$ . This feature allows access to large *lig\_kern* arrays, because the first instruction must otherwise appear in a location  $\leq 255$ .

Any instruction with  $skip_byte > 128$  in the  $lig_kern$  array must have  $256 * op_byte + remainder < nl$ . If such an instruction is encountered during normal program execution, it denotes an unconditional halt; no ligature or kerning command is performed.

**define** *stop\_flag* = 128 { value indicating 'STOP' in a lig/kern program } **define** *kern\_flag* = 128 { op code for a kern step }

**43.** Extensible characters are specified by an *extensible\_recipe*, which consists of four bytes called *top*, *mid*, *bot*, and *rep* (in this order). These bytes are the character codes of individual pieces used to build up a large symbol. If *top*, *mid*, or *bot* are zero, they are not present in the built-up result. For example, an extensible vertical line is like an extensible bracket, except that the top and bottom pieces are missing.

44. The final portion of a TFM file is the *param* array, which is another sequence of *fix\_word* values.

- param[1] = slant is the amount of italic slant. For example, slant = .25 means that when you go up one unit, you also go .25 units to the right. The *slant* is a pure number; it's the only *fix\_word* other than the design size itself that is not scaled by the design size.
- param[2] = space is the normal spacing between words in text. Note that character " $_{\sqcup}$ " in the font need not have anything to do with blank spaces.
- $param[3] = space\_stretch$  is the amount of glue stretching between words.
- $param[4] = space\_shrink$  is the amount of glue shrinking between words.
- $param[5] = x_h height$  is the height of letters for which accents don't have to be raised or lowered.
- param[6] = quad is the size of one em in the font.

 $param[7] = extra_space$  is the amount added to param[2] at the ends of sentences.

When the character coding scheme is GFGRAY or GFSLANT, the font is supposed to contain an additional parameter called *default\_rule\_thickness*. Other special parameters go with other coding schemes.

45. Input from binary files. We have seen that GF and DVI and TFM files are sequences of 8-bit bytes. The bytes appear physically in what is called a 'packed file of 0...255' in Pascal lingo.

Packing is system dependent, and many Pascal systems fail to implement such files in a sensible way (at least, from the viewpoint of producing good production software). For example, some systems treat all byte-oriented files as text, looking for end-of-line marks and such things. Therefore some system-dependent code is often needed to deal with binary files, even though most of the program in this section of GFtoDVI is written in standard Pascal.

One common way to solve the problem is to consider files of *integer* numbers, and to convert an integer in the range  $-2^{31} \le x < 2^{31}$  to a sequence of four bytes (a, b, c, d) using the following code, which avoids the controversial integer division of negative numbers:

> if  $x \ge 0$  then  $a \leftarrow x \operatorname{div} (100000000)$ else begin  $x \leftarrow (x + (1000000000)) + (1000000000); a \leftarrow x \operatorname{div} (100000000) + 128;$ end ;  $x \leftarrow x \operatorname{mod} (100000000);$  $b \leftarrow x \operatorname{div} (200000); x \leftarrow x \operatorname{mod} (200000);$  $c \leftarrow x \operatorname{div} (400); d \leftarrow x \operatorname{mod} (400);$

The four bytes are then kept in a buffer and output one by one. (On 36-bit computers, an additional division by 16 is necessary at the beginning. Another way to separate an integer into four bytes is to use/abuse Pascal's variant records, storing an integer and retrieving bytes that are packed in the same place; *caveat implementor!*) It is also desirable in some cases to read a hundred or so integers at a time, maintaining a larger buffer.

We shall stick to simple Pascal in this program, for reasons of clarity, even if such simplicity is sometimes unrealistic.

 $\langle \text{Types in the outer block } 9 \rangle + \equiv eight\_bits = 0..255;$  { unsigned one-byte quantity } byte\_file = packed file of eight\\_bits; { files that contain binary data }

46. The program deals with three binary file variables:  $gf_{-file}$  is the main input file that we are converting into a document;  $dvi_{-file}$  is the main output file that will specify that document; and  $tfm_{-file}$  is the current font metric file from which character-width information is being read.

 $\langle \text{Globals in the outer block } 12 \rangle +\equiv$   $gf_file: byte_file; \{ \text{the character data we are reading } \}$   $dvi_file: byte_file; \{ \text{the typesetting instructions we are writing } \}$  $tfm_file: byte_file; \{ \text{a font metric file } \}$ 

47. To prepare these files for input or output, we reset or rewrite them. An extension of Pascal is needed, since we want to associate it with external files whose names are specified dynamically (i.e., not known at compile time). The following code assumes that 'reset(f, s)' and 'rewrite(f, s)' do this, when f is a file variable and s is a string variable that specifies the file name.

```
procedure open_gf_file; { prepares to read packed bytes in gf_file } begin reset(gf_file, name_of_file); cur_loc \leftarrow 0; end;
```

procedure open\_tfm\_file; { prepares to read packed bytes in tfm\_file }
begin reset(tfm\_file, name\_of\_file);
end;

procedure open\_dvi\_file; { prepares to write packed bytes in dvi\_file }
begin rewrite(dvi\_file, name\_of\_file);
end;

**48.** If you looked carefully at the preceding code, you probably asked, "What are *cur\_loc* and *name\_of\_file*?" Good question. They are global variables: The integer *cur\_loc* tells which byte of the input file will be read next, and the string *name\_of\_file* will be set to the current file name before the file-opening procedures are called.

 $\langle \text{Globals in the outer block } 12 \rangle +\equiv cur\_loc: integer; { current byte number in gf_file } name\_of\_file: packed array [1...file\_name\_size] of char; { external file name }$ 

**49.** It turns out to be convenient to read four bytes at a time, when we are inputting from TFM files. The input goes into global variables b0, b1, b2, and b3, with b0 getting the first byte and b3 the fourth. (Globals in the outer block 12)  $+\equiv$ 

 $b0, b1, b2, b3: eight_bits; { four bytes input at once }$ 

**50.** The *read\_tfm\_word* procedure sets b0 through b3 to the next four bytes in the current TFM file. **procedure** *read\_tfm\_word*;

**begin** read(tfm\_file, b0); read(tfm\_file, b1); read(tfm\_file, b2); read(tfm\_file, b3); end;

**51.** We shall use another set of simple functions to read the next byte or bytes from  $gf_{-file}$ . There are four possibilities, each of which is treated as a separate function in order to minimize the overhead for subroutine calls.

**function** *qet\_byte*: *integer*; { returns the next byte, unsigned } **var** b: eight\_bits; **begin if**  $eof(gf_file)$  **then**  $get_byte \leftarrow 0$ else begin  $read(gf_file, b); incr(cur_loc); get_byte \leftarrow b;$ end: end; **function** get\_two\_bytes: integer; { returns the next two bytes, unsigned } **var** a, b: eight\_bits; **begin** read  $(qf_{file}, a)$ ; read  $(qf_{file}, b)$ ; cur\_loc  $\leftarrow$  cur\_loc + 2; get\_two\_bytes  $\leftarrow a * 256 + b$ ; end; **function** *get\_three\_bytes: integer;* { returns the next three bytes, unsigned } **var** a, b, c: eight\_bits; **begin**  $read(gf_file, a); read(gf_file, b); read(gf_file, c); cur_loc \leftarrow cur_loc + 3;$  $qet\_three\_bytes \leftarrow (a * 256 + b) * 256 + c;$ end; **function** signed\_quad: integer; { returns the next four bytes, signed } **var** a, b, c, d: *eight\_bits*; **begin** read  $(qf_{file}, a)$ ; read  $(qf_{file}, b)$ ; read  $(qf_{file}, c)$ ; read  $(qf_{file}, d)$ ; cur\_loc  $\leftarrow$  cur\_loc + 4; if a < 128 then signed\_quad  $\leftarrow ((a * 256 + b) * 256 + c) * 256 + d$ else  $signed_quad \leftarrow (((a - 256) * 256 + b) * 256 + c) * 256 + d;$ 

52. Reading the font information. Now let's get down to brass tacks and consider the more substantial routines that actually convert TFM data into a form suitable for computation. The routines in this part of the program have been borrowed from  $T_EX$ , with slight changes, since GFtoDVI has to do some of the things that  $T_EX$  does.

The TFM data is stored in a large array called *font\_info*. Each item of *font\_info* is a *memory\_word*; the *fix\_word* data gets converted into *scaled* entries, while everything else goes into words of type *four\_quarters*. (These data structures are special cases of the more general memory words of T<sub>E</sub>X. On some machines it is necessary to define *min\_quarterword* = -128 and *max\_quarterword* = 127 in order to pack four quarterwords into a single word.)

```
define min_quarterword = 0 { change this to allow efficient packing, if necessary }
  define max_quarterword = 255  { ditto }
  define qi(\#) \equiv \# + min_quarterword { to put an eight_bits item into a quarterword }
  define qo(\#) \equiv \# - min_quarterword { to take an eight_bits item out of a quarterword }
  define title_font = 1
  define label_font = 2
 define gray_font = 3
  define slant_font = 4
  define logo_font = 5
  define non_char \equiv qi(256)
  define non_address \equiv font_mem_size
\langle \text{Types in the outer block } 9 \rangle + \equiv
 font\_index = 0 \dots font\_mem\_size; quarterword = min\_quarterword \dots max\_quarterword; \{1/4 \text{ of a word}\}
 four_quarters = packed record b0: quarterword;
    b1: quarterword;
    b2: quarterword;
    b3: quarterword;
    end:
  memory_word = record
    case boolean of
    true: (sc : scaled);
    false: (qqqq : four_quarters);
    end:
  internal_font_number = title_font .. logo_font;
```

 ${
m GF}$  to  ${
m DVI}$  §53

**53.** Besides  $font\_info$ , there are also a number of index arrays that point into it, so that we can locate width and height information, etc. For example, the  $char\_info$  data for character c in font f will be in  $font\_info[char\_base[f] + c].qqqq$ ; and if w is the  $width\_index$  part of this word (the b0 field), the width of the character is  $font\_info[width\_base[f] + w].sc$ . (These formulas assume that  $min\_quarterword$  has already been added to w, but not to c.)

 $\langle \text{Globals in the outer block } 12 \rangle + \equiv$ 

font\_info: **array** [font\_index] **of** memory\_word; { the font metric data } *fmem\_ptr: font\_index;* { first unused word of *font\_info* } font\_check: **array** [internal\_font\_number] **of** four\_quarters; { check sum } font\_size: **array** [internal\_font\_number] **of** scaled; { "at" size } font\_dsize: **array** [internal\_font\_number] **of** scaled; { "design" size } { beginning (smallest) character code } font\_bc: **array** [internal\_font\_number] **of** eight\_bits; font\_ec: **array** [internal\_font\_number] **of** eight\_bits; { ending (largest) character code } { base addresses for *char\_info* } char\_base: **array** [internal\_font\_number] **of** integer; width\_base: **array** [internal\_font\_number] **of** integer; { base addresses for widths } *height\_base:* **array** [*internal\_font\_number*] **of** *integer*; { base addresses for heights } depth\_base: **array** [internal\_font\_number] **of** integer; { base addresses for depths } *italic\_base:* **array** [*internal\_font\_number*] **of** *integer*; { base addresses for italic corrections } *liq\_kern\_base:* **array** [*internal\_font\_number*] **of** *integer*; { base addresses for ligature/kerning programs } kern\_base: **array** [internal\_font\_number] **of** integer; { base addresses for kerns } exten\_base: **array** [internal\_font\_number] **of** integer; { base addresses for extensible recipes } param\_base: **array** [internal\_font\_number] **of** integer; { base addresses for font parameters } bchar\_label: **array** [internal\_font\_number] **of** font\_index; { start of *lig\_kern* program for left boundary character, *non\_address* if there is none }

font\_bchar: **array** [internal\_font\_number] **of** min\_quarterword .. non\_char;

{right boundary character, *non\_char* if there is none }

54.  $\langle \text{Set initial values } 13 \rangle + \equiv fmem_ptr \leftarrow 0;$ 

**55.** Of course we want to define macros that suppress the detail of how font information is actually packed, so that we don't have to write things like

 $font_info[width_base[f] + font_info[char_base[f] + c].qqqq.b0].sc$ 

too often. The WEB definitions here make  $char_info(f)(c)$  the four\_quarters word of font information corresponding to character c of font f. If q is such a word,  $char_width(f)(q)$  will be the character's width; hence the long formula above is at least abbreviated to

 $char_width(f)(char_info(f)(c)).$ 

In practice we will try to fetch q first and look at several of its fields at the same time.

The italic correction of a character will be denoted by  $char_italic(f)(q)$ , so it is analogous to  $char_width$ . But we will get at the height and depth in a slightly different way, since we usually want to compute both height and depth if we want either one. The value of  $height_depth(q)$  will be the 8-bit quantity

 $b = height_index \times 16 + depth_index,$ 

and if b is such a byte we will write  $char_height(f)(b)$  and  $char_depth(f)(b)$  for the height and depth of the character c for which  $q = char_info(f)(c)$ . Got that?

The tag field will be called *char\_tag(q)*; and the remainder byte will be called *rem\_byte(q)*.

**define**  $char_info_end(\#) \equiv \#$  ] .qqqq **define**  $char_info(\#) \equiv font_info [ char_base[\#] + char_info_end$ define  $char_width_end(\#) \equiv \#.b0$  ].sc define  $char_width(\#) \equiv font_info [width_base[\#] + char_width_end$ define  $char_exists(\#) \equiv (\#.b0 > min_quarterword)$ define  $char_italic_end(\#) \equiv (qo(\#.b2)) \operatorname{div} 4 ]$ .sc **define**  $char_italic(\#) \equiv font_info$  [  $italic_base[\#] + char_italic_end$ define  $height\_depth(\#) \equiv qo(\#.b1)$ define  $char_height_end(\#) \equiv (\#) \operatorname{div} 16$ ].sc **define**  $char_height(\#) \equiv font_info [ height_base[\#] + char_height_end$ define  $char_depth_end(\#) \equiv \# \mod 16$  ].sc define  $char_depth(\#) \equiv font_info \ [depth_base[\#] + char_depth_end$ define  $char_tag(\#) \equiv ((qo(\#.b2)) \mod 4)$ **define**  $skip_byte(\texttt{#}) \equiv qo(\texttt{#}.b\theta)$ define  $next_char(\#) \equiv \#.b1$ define  $op_byte(\#) \equiv qo(\#.b2)$ define  $rem_byte(\#) \equiv \#.b3$ 

56. Here are some macros that help process ligatures and kerns. We write  $char_kern(f)(j)$  to find the amount of kerning specified by kerning command j in font f.

 $\begin{array}{l} \textbf{define} \quad lig\_kern\_start(\texttt{\#}) \equiv lig\_kern\_base[\texttt{\#}] + rem\_byte \quad \{ \text{ beginning of lig/kern program } \} \\ \textbf{define} \quad lig\_kern\_restart\_end(\texttt{\#}) \equiv 256 * (op\_byte(\texttt{\#})) + rem\_byte(\texttt{\#}) \\ \textbf{define} \quad lig\_kern\_restart(\texttt{\#}) \equiv lig\_kern\_base[\texttt{\#}] + lig\_kern\_restart\_end \\ \textbf{define} \quad char\_kern\_end(\texttt{\#}) \equiv 256 * (op\_byte(\texttt{\#}) - 128) + rem\_byte(\texttt{\#}) \ ] .sc \\ \textbf{define} \quad char\_kern(\texttt{\#}) \equiv font\_info \ [ kern\_base[\texttt{\#}] + char\_kern\_end \\ \end{array}$ 

**57.** Font parameters are referred to as slant(f), space(f), etc.

define  $param\_end(#) \equiv param\_base[#]$ ].sc define  $param(#) \equiv font\_info [ # + param\_end$ define  $slant \equiv param(1)$  { slant to the right, per unit distance upward } define  $space \equiv param(2)$  { normal space between words } define  $x\_height \equiv param(5)$  { one ex } define  $default\_rule\_thickness \equiv param(8)$  { thickness of rules }

**58.** Here is the subroutine that inputs the information on  $tfm_file$ , assuming that the file has just been reset. Parameter f tells which metric file is being read (either *title\_font* or *label\_font* or *gray\_font* or *slant\_font* or *logo\_font*); parameter s is the "at" size, which will be substituted for the design size if it is positive.

This routine does only limited checking of the validity of the file, because another program (TFtoPL) is available to diagnose errors in the rare case that something is amiss.

**define**  $bad\_tfm = 11$  { label for  $read\_font\_info$  } **define**  $abend \equiv$  **goto**  $bad\_tfm$  { do this when the TFM data is wrong }

procedure read\_font\_info(f : integer; s : scaled); { input a TFM file }

else  $bchar\_label[f] \leftarrow non\_address;$ 

 $font\_bchar[f] \leftarrow qi(bchar); adjust(width\_base); adjust(lig\_kern\_base); adjust(kern\_base); adjust(kern\_base); adjust(exten\_base); decr(param\_base[f]); fmem\_ptr \leftarrow fmem\_ptr + lf; goto done$ 

This code is used in section 59.

## §70 GF to DVI

70. The string pool. GFtoDVI remembers strings by putting them into an array called *str\_pool*. The *str\_start* array tells where each string starts in the pool.

 $\langle \text{Types in the outer block } 9 \rangle + \equiv$   $pool_pointer = 0 \dots pool_size; \{ \text{for variables that point into } str_pool \}$  $str_number = 0 \dots max\_strings; \{ \text{for variables that point into } str\_start \}$ 

**71.** As new strings enter, we keep track of the storage currently used, by means of two global variables called *pool\_ptr* and  $str_ptr$ . These are periodically reset to their initial values when we move from one character to another, because most strings are of only temporary interest.

 $\langle \text{Globals in the outer block 12} \rangle +\equiv str_pool: packed array [pool_pointer] of ASCII_code; { the characters } str_start: array [str_number] of pool_pointer; { the starting pointers } pool_ptr: pool_pointer; { first unused position in str_pool } str_ptr: str_number; { start of the current string being created } init_str_ptr: str_number; { str_ptr setting when a new character starts }$ 

72. Several of the elementary string operations are performed using WEB macros instead of using Pascal procedures, because many of the operations are done quite frequently and we want to avoid the overhead of procedure calls. For example, here is a simple macro that computes the length of a string.

define  $length(\#) \equiv (str\_start[\#+1] - str\_start[\#])$  { the number of characters in string number # }

**73.** Strings are created by appending character codes to *str\_pool*. The macro called *append\_char*, defined here, does not check to see if the value of *pool\_ptr* has gotten too high; that test is supposed to be made before *append\_char* is used.

To test if there is room to append l more characters to  $str_pool$ , we shall write  $str_room(l)$ , which aborts GFtoDVI and gives an apologetic error message if there isn't enough room.

define append\_char(#) ≡ { put ASCII\_code # at the end of str\_pool }
 begin str\_pool[pool\_ptr] ← #; incr(pool\_ptr);
 end
define str\_room(#) ≡ { make sure that the pool hasn't overflowed }
 begin if pool\_ptr + # > pool\_size then abort(`Tooumanyustrings!`);
 end

**74.** Once a sequence of characters has been appended to *str\_pool*, it officially becomes a string when the function *make\_string* is called. This function returns the identification number of the new string as its value.

function make\_string: str\_number; { current string enters the pool }
begin if str\_ptr = max\_strings then abort(`Tooumanyulabels!`);
incr(str\_ptr); str\_start[str\_ptr] \leftarrow pool\_ptr; make\_string \leftarrow str\_ptr - 1;
end;

75. The first strings in the string pool are the keywords that GFtoDVI recognizes in the xxx commands of a GF file. They are entered into str\_pool by means of a tedious bunch of assignment statements, together with calls on the *first\_string* subroutine.

```
define init\_str\theta(\#) \equiv first\_string(\#)
  define init\_str1 (#) \equiv buffer[1] \leftarrow #; init\_str0
   define init\_str2(\#) \equiv buffer[2] \leftarrow \#; init\_str1
   define init\_str3(\#) \equiv buffer[3] \leftarrow \#; init\_str2
   define init\_str4 (#) \equiv buffer[4] \leftarrow #; init\_str3
   define init\_str5(\#) \equiv buffer[5] \leftarrow \#; init\_str4
   define init\_str6(\#) \equiv buffer[6] \leftarrow \#; init\_str5
   define init\_str7(\#) \equiv buffer[7] \leftarrow \#; init\_str6
   define init\_str8(\#) \equiv buffer[8] \leftarrow \#; init\_str7
  define init\_str9(\texttt{#}) \equiv buffer[9] \leftarrow \texttt{#}; init\_str8
   define init\_str10(\#) \equiv buffer[10] \leftarrow \#; init\_str9
   define init\_str11(\texttt{#}) \equiv buffer[11] \leftarrow \texttt{#}; init\_str10
   define init\_str12(\texttt{#}) \equiv buffer[12] \leftarrow \texttt{#}; init\_str11
   define init\_str13(\#) \equiv buffer[13] \leftarrow \#; init\_str12
   define longest_keyword = 13
procedure first\_string(c:integer);
   begin if str_ptr \neq c then abort(??); { internal consistency check }
   while l > 0 do
      begin append\_char(buffer[l]); decr(l);
      end:
   incr(str_ptr); str_start[str_ptr] \leftarrow pool_ptr;
   end;
```

**76.**  $\langle$  Globals in the outer block  $12 \rangle +\equiv$ *l: integer*; { length of string being made by *first\_string* }

```
77. Here are the tedious assignments just promised. String number 0 is the empty string.
```

**define**  $null\_string = 0$  { the empty keyword } **define**  $area\_code = 4$  { add to font code for the 'area' keywords } **define**  $at\_code = 8$  { add to font code for the 'at' keywords } **define**  $rule\_code = 13$  { code for the keyword 'rule' } **define** *title\_code* = 14 { code for the keyword 'title' } **define** *rule\_thickness\_code* = 15 { code for the keyword 'rulethickness' } **define** *offset\_code* = 16 { code for the keyword 'offset' } define  $x_{offset\_code} = 17$  { code for the keyword 'xoffset' } **define**  $y_{offset_code} = 18$  { code for the keyword 'yoffset' } **define**  $max\_keyword = 18$  { largest keyword code number }  $\langle \text{Initialize the strings } 77 \rangle \equiv$  $str_ptr \leftarrow 0; \ pool_ptr \leftarrow 0; \ str_start[0] \leftarrow 0;$  $l \leftarrow 0$ ; *init\_str0* (*null\_string*);  $l \leftarrow 9$ ;  $init\_str9("t")("i")("t")("l")("e")("f")("o")("n")("t")(title\_font)$ ;  $l \leftarrow 9; init\_str9("l")("a")("b")("e")("l")("f")("o")("n")("t")(label\_font);$  $l \leftarrow 8; init\_str8("g")("r")("a")("y")("f")("o")("n")("t")(gray\_font);$  $l \leftarrow 9; init\_str9("s")("l")("a")("n")("t")("f")("o")("n")("t")(slant\_font);$  $l \leftarrow 13$ : *init\_str13*("t")("t")("t")("l")("e")("f")("o")("n")("t")("a")("r")("e")("a")(*title\_font* + *area\_code*);  $l \leftarrow 13;$ *init\_str13*("l")("a")("b")("e")("l")("f")("o")("n")("t")("a")("r")("e")("a")(*label\_font* + *area\_code*);  $l \leftarrow 12;$ *init\_str12*("g")("r")("a")("y")("f")("o")("n")("t")("a")("r")("e")("a")(*gray\_font + area\_code*);  $l \leftarrow 13$ : init\_str13("s")("l")("a")("n")("t")("f")("o")("n")("t")("a")("r")("e")("a")(slant\_font + area\_code);  $l \leftarrow 11; init\_str11("t")("i")("t")("t")("f")("o")("n")("t")("a")("t")(title\_font + at\_code);$  $l \leftarrow 11; init\_str11("l")("a")("b")("e")("l")("f")("o")("n")("t")("a")("t")(label\_font + at\_code);$  $l \leftarrow 10; init\_str10("g")("r")("a")("y")("f")("o")("n")("t")("a")("t")(gray\_font + at\_code);$  $l \leftarrow 11; init\_str11("s")("l")("a")("t")("t")("f")("o")("n")("t")("a")("t")(slant\_font + at\_code);$  $l \leftarrow 4$ ; *init\_str4* ("**r**")("**u**")("**1**")("**e**")(*rule\_code*);  $l \leftarrow 5; init\_str5("t")("i")("t")("l")("e")(title\_code);$  $l \leftarrow 13$ : *init\_str13*("r")("u")("l")("e")("t")("h")("i")("c")("k")("n")("e")("s")("s")(*rule\_thickness\_code*);  $l \leftarrow 6$ ; *init\_str6* ("o")("f")("f")("s")("e")("t")(offset\_code);  $l \leftarrow 7$ ; *init\_str7*("x")("o")("f")("f")("s")("e")("t")(x\_offset\_code);  $l \leftarrow 7$ ;  $init\_str7("y")("o")("f")("f")("s")("e")("t")(y_offset\_code)$ ; See also sections 78 and 88.

This code is used in section 219.

**78.** We will also find it useful to have the following strings. (The names of default fonts will presumably be different at different sites.)

```
define g_{f}-ext = max_keyword + 1 { string number for '.gf'}
  define dv_{i}ext = max_keyword + 2 { string number for '.dvi'}
  define tfm_ext = max_keyword + 3 { string number for '.tfm' }

More precisely, we assume that  $cur_gf$  contains an op-code byte just read from the GF file, where  $xxx1 \leq cur_gf \leq no_op$ . The *interpret\_xxx* procedure will read the rest of the command, in the following way:

- 1) If *cur\_gf* is *no\_op* or *yyy*, or if it's an *xxx* command with an unknown keyword, the bytes are simply read and ignored, and the value *no\_operation* is returned.
- 2) If  $cur_gf$  is an xxx command (either xxx1 or  $\cdots$  or xxx4), and if the associated string matches a keyword exactly, the string number of that keyword is returned (e.g.,  $rule_thickness\_code$ ).
- 3) If *cur\_gf* is an *xxx* command whose string begins with keyword and space, the string number of that keyword is returned, and the remainder of the string is put into the string pool (where it will be string number *cur\_string*. Exception: If the keyword is *null\_string*, the character immediately following the blank space is put into the global variable *label\_type*, and the remaining characters go into the string pool.
- In all cases, *cur\_gf* will then be reset to the op-code byte that immediately follows the original command.

define  $no_operation = max_keyword + 1$ 

 $\langle \text{Types in the outer block } 9 \rangle + \equiv$ keyword\_code = null\_string ... no\_operation;

80. (Globals in the outer block 12)  $+\equiv$ 

cur\_gf: eight\_bits; { the byte most recently read from gf\_file }
cur\_string: str\_number; { the string following a keyword and space }
label\_type: eight\_bits; { the character following a null keyword and space }

81. We will be using this procedure when reading the GF file just after the preamble and just after *eoc* commands.

**function** *interpret\_xxx*: *keyword\_code*; **label** *done*, *done1*, *not\_found*; **var** k: *integer*; { number of bytes in an xxx command } *j*: *integer*; { number of bytes read so far } *l*: 0...*longest\_keyword*; { length of keyword to check } *m*: *keyword\_code*; { runs through the list of known keywords } *n1*: 0...*longest\_keyword*; { buffered character being checked } *n2*: *pool\_pointer*; { pool character being checked } c: keyword\_code; { the result to return } **begin**  $c \leftarrow no_operation; cur\_string \leftarrow null\_string;$ case cur\_gf of *no\_op*: goto *done*; *yyy*: **begin**  $k \leftarrow signed\_quad$ ; **goto** *done*; end:  $xxx1: k \leftarrow get\_byte;$  $xxx2: k \leftarrow get_two_bytes;$ *xxx3*:  $k \leftarrow get\_three\_bytes$ ;  $xxx4: k \leftarrow signed_quad;$ **end**; { there are no other cases } (Read the next k characters of the GF file; change c and goto done if a keyword is recognized 82); done:  $cur_qf \leftarrow get_byte$ ;  $interpret_xxx \leftarrow c$ ;

end;

82. (Read the next k characters of the GF file; change c and goto done if a keyword is recognized 82)  $\equiv j \leftarrow 0$ ; if k < 2 then goto not\_found;

loop begin  $l \leftarrow j$ ; if j = k then goto done1; if  $j = longest\_keyword$  then goto not\_found; incr(j);  $buffer[j] \leftarrow get\_byte$ ; if  $buffer[j] = "\_"$  then goto done1; end; done1: (If the keyword in buffer[1 ... l] is known, change c and goto done 83); not\_found: while j < k do begin incr(j);  $cur\_gf \leftarrow get\_byte$ ; end

This code is used in section 81.

```
(If the keyword in buffer [1 \dots l] is known, change c and goto done \{83\}) \equiv
83.
  for m \leftarrow null\_string to max_keyword do
    if length(m) = l then
       begin n1 \leftarrow 0; n2 \leftarrow str\_start[m];
       while (n1 < l) \land (buffer[n1 + 1] = str_pool[n2]) do
          begin incr(n1); incr(n2);
         end;
       if n1 = l then
         begin c \leftarrow m;
         if m = null\_string then
            begin incr(j); label_type \leftarrow get_byte;
            end;
          str_room(k-j);
          while j < k do
            begin incr(j); append_char(get_byte);
            end:
          cur\_string \leftarrow make\_string; goto done;
          end;
       end
```

This code is used in section 82.

**84.** When an *xxx* command takes a numeric argument, *get\_yyy* reads that argument and puts the following byte into *cur\_gf*.

```
function get_yyy: scaled;

var v: scaled; {value just read}

begin if cur_gf \neq yyy then get_yyy \leftarrow 0

else begin v \leftarrow signed_quad; cur_gf \leftarrow get_byte; get_yyy \leftarrow v;

end;

end;
```

85. A simpler method is used for special commands between *boc* and *eoc*, since GFtoDVI doesn't even look at them.

```
procedure skip_nop;
```

```
label done;
var k: integer; { number of bytes in an xxx command }
    j: integer; { number of bytes read so far }
begin case cur_gf of
    no_op: goto done;
    yyy: begin k \leftarrow signed_quad; goto done;
    end;
    xxx1: k \leftarrow get_byte;
    xxx2: k \leftarrow get_two_bytes;
    xxx3: k \leftarrow get_three_bytes;
    xxx4: k \leftarrow signed_quad;
end; { there are no other cases }
    for j \leftarrow 1 to k do cur_gf \leftarrow get_byte;
done: cur_gf \leftarrow get_byte;
end;
```

86. File names. It's time now to fret about file names. GFtoDVI uses the conventions of T<sub>E</sub>X and META-FONT to convert file names into strings that can be used to open files. Three routines called *begin\_name*, *more\_name*, and *end\_name* are involved, so that the system-dependent parts of file naming conventions are isolated from the system-independent ways in which file names are used. (See the T<sub>E</sub>X or METAFONT program listing for further explanation.)

 $\langle \text{Globals in the outer block } 12 \rangle +\equiv cur\_name: str\_number; { name of file just scanned } cur\_area: str\_number; { file area just scanned, or null\_string } cur\_ext: str\_number; { file extension just scanned, or null\_string }$ 

87. The file names we shall deal with for illustrative purposes have the following structure: If the name contains '>' or ':', the file area consists of all characters up to and including the final such character; otherwise the file area is null. If the remaining file name contains '.', the file extension consists of all such characters from the first remaining '.' to the end, otherwise the file extension is null.

We can such file names easily by using two global variables that keep track of the occurrences of area and extension delimiters:

 $\langle \text{Globals in the outer block } 12 \rangle +\equiv$ area\_delimiter: pool\_pointer; { the most recent '>' or ':', if any } ext\_delimiter: pool\_pointer; { the relevant '.', if any }

**88.** Font metric files whose areas are not given explicitly are assumed to appear in a standard system area called *home\_font\_area*. This system area name will, of course, vary from place to place. The program here sets it to 'TeXfonts:'.

 $\langle \text{Initialize the strings 77} \rangle +\equiv l \leftarrow 9; init\_str9("T")("e")("X")("f")("o")("n")("t")("s")(":")(home\_font\_area);$ 

89. Here now is the first of the system-dependent routines for file name scanning.

```
procedure begin_name;

begin area_delimiter \leftarrow 0; ext_delimiter \leftarrow 0;

end;
```

**90.** And here's the second.

```
function more\_name(c: ASCII\_code): boolean;

begin if c = "_{\sqcup}" then more\_name \leftarrow false

else begin if (c = ">") \lor (c = ":") then

begin area\_delimiter \leftarrow pool\_ptr; ext\_delimiter \leftarrow 0;

end

else if (c = ".") \land (ext\_delimiter = 0) then ext\_delimiter \leftarrow pool\_ptr;

str\_room(1); append\_char(c); { contribute c to the current string }

more\_name \leftarrow true;

end;

end;
```

### 91. The third.

```
procedure end_name;
begin if str_ptr + 3 > max_strings then abort(`Too∟many⊔strings!`);
if area_delimiter = 0 then cur_area ← null_string
else begin cur_area ← str_ptr; incr(str_ptr); str_start[str_ptr] ← area_delimiter + 1;
end;
if ext_delimiter = 0 then
begin cur_ext ← null_string; cur_name ← make_string;
end
else begin cur_name ← str_ptr; incr(str_ptr); str_start[str_ptr] ← ext_delimiter;
cur_ext ← make_string;
end;
end;
end;
```

**92.** Another system-dependent routine is needed to convert three strings into the *name\_of\_file* value that is used to open files. The present code allows both lowercase and uppercase letters in the file name.

```
define append_to_name(\#) \equiv

begin \ c \leftarrow \#; \ incr(k);

if k \leq file_name_size then name_of_file[k] \leftarrow xchr[c];

end
```

**procedure**  $pack_file_name(n, a, e: str_number);$ 

**var** k: integer; { number of positions filled in name\_of\_file } c: ASCII\_code; { character being packed } j: integer; { index into str\_pool } name\_length: 0.. file\_name\_size; { number of characters packed } **begin**  $k \leftarrow 0$ ; for  $j \leftarrow str_start[a]$  to  $str_start[a+1] - 1$  do  $append_to_name(str_pool[j])$ ; for  $j \leftarrow str_start[n]$  to  $str_start[n+1] - 1$  do  $append_to_name(str_pool[j])$ ; for  $j \leftarrow str_start[e]$  to  $str_start[e+1] - 1$  do  $append_to_name(str_pool[j])$ ; for  $j \leftarrow str_start[e]$  to  $str_start[e+1] - 1$  do  $append_to_name(str_pool[j])$ ; if  $k \leq file_name_size$  then  $name_length \leftarrow k$  else  $name_length \leftarrow file_name_size$ ; for  $k \leftarrow name_length + 1$  to  $file_name_size$  do  $name_of_file[k] \leftarrow ``u`$ ; end;

**93.** Now let's consider the routines by which GFtoDVI deals with file names in a system-independent manner. The global variable *job\_name* contains the GF file name that is being input. This name is extended by 'dvi' in order to make the name of the output file.

 $\langle \text{Globals in the outer block } 12 \rangle +\equiv job\_name: str\_number; { principal file name }$ 

**94.** The *start\_gf* procedure prompts the user for the name of the generic font file to be input. It opens the file, making sure that some input is present; then it opens the output file.

Although this routine is system-independent, it should probably be modified to take the file name from the command line (without an initial prompt), on systems that permit such things.

# procedure start\_gf;

label found, done; begin loop begin print\_nl(`GF\_lfile\_name:\_\_`); input\_ln; buf\_ptr ← 0; buffer[line\_length] ← "?"; while buffer[buf\_ptr] = "\_" do incr(buf\_ptr); if buf\_ptr < line\_length then begin (Scan the file name in the buffer 95); if cur\_ext = null\_string then cur\_ext ← gf\_ext; pack\_file\_name(cur\_name, cur\_area, cur\_ext); open\_gf\_file; if ¬eof(gf\_file) then goto found; print\_nl(`Oops...\_IL\_can``t\_find\_file\_'); print(name\_of\_file); end; end;

found:  $job\_name \leftarrow cur\_name$ ;  $pack\_file\_name(job\_name, null\_string, dvi\_ext)$ ;  $open\_dvi\_file$ ; end;

95. (Scan the file name in the buffer 95) ≡
if buffer[line\_length - 1] = "/" then
 begin interaction ← true; decr(line\_length);
 end;
 begin\_name;
 loop begin if buf\_ptr = line\_length then goto done;
 if ¬more\_name(buffer[buf\_ptr]) then goto done;
 incr(buf\_ptr);
 end;
done: end\_name

This code is used in section 94.

**96.** Special instructions found near the beginning of the GF file might change the names, areas, and "at" sizes of the fonts that GFtoDVI will be using. But when we reach the first *boc* instruction, we input all of the TFM files. The global variable *interaction* is set *true* if a "/" was removed at the end of the file name; this means that the user will have a chance to issue special instructions online just before the fonts are loaded.

**define**  $check\_fonts \equiv \mathbf{if} \ fonts\_not\_loaded \ \mathbf{then} \ load\_fonts$ 

 $\langle \text{Globals in the outer block } 12 \rangle +\equiv$ interaction: boolean; { is the user allowed to type specials online? } fonts\_not\_loaded: boolean; { have the TFM files still not been input? } font\_name: array [internal\_font\_number] of str\_number; { current font names } font\_area: array [internal\_font\_number] of str\_number; { current font areas } font\_at: array [internal\_font\_number] of scaled; { current font "at" sizes }

**97.**  $\langle$  Set initial values  $13 \rangle + \equiv$ 

 $interaction \leftarrow false; fonts\_not\_loaded \leftarrow true; font\_name[title\_font] \leftarrow default\_title\_font; font\_name[label\_font] \leftarrow default\_label\_font; font\_name[gray\_font] \leftarrow default\_gray\_font; font\_name[slant\_font] \leftarrow null\_string; font\_name[logo\_font] \leftarrow logo\_font\_name; for k \leftarrow title\_font to logo\_font do$  $begin font\_area[k] \leftarrow null\_string; font\_at[k] \leftarrow 0; end;$  **98.** After the following procedure has been performed, there will be no turning back; the fonts will have been firmly established in GFtoDVI's memory.

```
\langle \text{Declare the procedure called } load_fonts | 98 \rangle \equiv
procedure load_fonts;
  label done, continue, found, not_found;
  var f: internal_font_number; i: four_quarters; { font information word }
     j, k, v: integer; { registers for initializing font tables }
     m: title_font .. slant_font + area_code; { keyword found }
     n1: 0... longest_keyword; { buffered character being checked }
     n2: pool_pointer; \{ pool character being checked \}
  begin if interaction then \langle Get online special input 99\rangle;
  fonts\_not\_loaded \leftarrow false;
  for f \leftarrow title\_font to logo\_font do
     if (f \neq slant_font) \lor (length(font_name[f]) > 0) then
       begin if length(font_area[f]) = 0 then font_area[f] \leftarrow home_font_area;
       pack_file_name(font_name[f], font_area[f], tfm_ext); open_tfm_file; read_font_info(f, font_at[f]);
       if font\_area[f] = home\_font\_area then font\_area[f] \leftarrow null\_string;
       dvi_font_def(f); { put the font name in the DVI file }
       end:
  (Initialize global variables that depend on the font data 137);
  end:
This code is used in section 111.
      \langle \text{Get online special input } 99 \rangle \equiv
99.
  loop begin not_found: print_nl(`Special_font_substitution:__`);
  continue: input_ln;

 begin append\_char(buffer[buf\_ptr]); incr(buf\_ptr);
end;
if m > area\_code then font\_area[m - area\_code] ← make\_string
else begin font\_name[m] ← make\_string; font\_area[m] ← null\_string; font\_at[m] ← 0;
end;
init\_str\_ptr ← str\_ptr
This code is used in section 99.

**102.** Shipping pages out. The following routines are used to write the DVI file. They have been copied from T<sub>F</sub>X, but simplified; we don't have to handle nearly as much generality as T<sub>F</sub>X does.

Statistics about the entire set of pages that will be shipped out must be reported in the DVI postamble. The global variables *total\_pages*, *max\_v*, *max\_h*, and *last\_bop* are used to record this information.

 $\langle \text{Globals in the outer block } 12 \rangle + \equiv$ 

total\_pages: integer; { the number of pages that have been shipped out }
max\_v: scaled; { maximum height-plus-depth of pages shipped so far }
max\_h: scaled; { maximum width of pages shipped so far }
last\_bop: integer; { location of previous bop in the DVI output }

**103.**  $\langle \text{Set initial values } 13 \rangle + \equiv$ total\_pages  $\leftarrow 0$ ; max\_v  $\leftarrow 0$ ; max\_h  $\leftarrow 0$ ; last\_bop  $\leftarrow -1$ ;

104. The DVI bytes are output to a buffer instead of being written directly to the output file. This makes it possible to reduce the overhead of subroutine calls.

The output buffer is divided into two parts of equal size; the bytes found in  $dvi_buf[0 \dots half_buf - 1]$  constitute the first half, and those in  $dvi_buf[half_buf \dots dvi_buf_size - 1]$  constitute the second. The global variable  $dvi_ptr$  points to the position that will receive the next output byte. When  $dvi_ptr$  reaches  $dvi_limit$ , which is always equal to one of the two values  $half_buf$  or  $dvi_buf_size$ , the half buffer that is about to be invaded next is sent to the output and  $dvi_limit$  is changed to its other value. Thus, there is always at least a half buffer's worth of information present, except at the very beginning of the job.

Bytes of the DVI file are numbered sequentially starting with 0; the next byte to be generated will be number  $dvi_offset + dvi_ptr$ .

 $\langle \text{Types in the outer block } 9 \rangle + \equiv dvi_i dex = 0 \dots dvi_b uf_size;$  { an index into the output buffer }

**105.** Some systems may find it more efficient to make *dvi\_buf* a **packed** array, since output of four bytes at once may be facilitated.

 $\langle \text{Globals in the outer block } 12 \rangle + \equiv \\ dvi_buf: \mathbf{array} [dvi_index] \mathbf{of} eight_bits; \{ \text{buffer for DVI output} \} \\ half_buf: dvi_index; \{ \text{half of } dvi_buf_size \} \\ dvi_limit: dvi_index; \{ \text{end of the current half buffer} \} \\ dvi_ptr: dvi_index; \{ \text{the next available buffer address} \} \\ dvi_offset: integer; \{ dvi_buf_size \text{ times the number of times the output buffer has been fully emptied} \}$ 

**106.** Initially the buffer is all in one piece; we will output half of it only after it first fills up.

 $\langle \text{Set initial values } 13 \rangle + \equiv \\ half_buf \leftarrow dvi_buf_size \operatorname{div} 2; dvi_limit \leftarrow dvi_buf_size; dvi_ptr \leftarrow 0; dvi_offset \leftarrow 0; \end{cases}$ 

107. The actual output of  $dvi_buf[a \dots b]$  to  $dvi_file$  is performed by calling  $write_dvi(a, b)$ . It is safe to assume that a and b + 1 will both be multiples of 4 when  $write_dvi(a, b)$  is called; therefore it is possible on many machines to use efficient methods to pack four bytes per word and to output an array of words with one system call.

```
procedure write_dvi(a, b : dvi_index);

var k: dvi_index;

begin for k \leftarrow a to b do write(dvi_file, dvi_buf[k]);

end;
```

To put a byte in the buffer without paying the cost of invoking a procedure each time, we use the 108. macro dvi\_out.

**define**  $dvi_out(\#) \equiv \mathbf{begin} \ dvi_buf[dvi_ptr] \leftarrow \#; \ incr(dvi_ptr);$ if  $dvi_ptr = dvi_limit$  then  $dvi_swap$ ; end **procedure** *dvi\_swap*; { outputs half of the buffer } **begin if**  $dvi_limit = dvi_buf_size$  then **begin** write\_dvi(0, half\_buf - 1); dvi\_limit  $\leftarrow$  half\_buf; dvi\_offset  $\leftarrow$  dvi\_offset + dvi\_buf\_size;  $dvi_ptr \leftarrow 0;$ end else begin write\_dvi(half\_buf, dvi\_buf\_size - 1); dvi\_limit \leftarrow dvi\_buf\_size; end;

end;

109. Here is how we clean out the buffer when  $T_{FX}$  is all through;  $dvi_ptr$  will be a multiple of 4.

 $\langle \text{Empty the last bytes out of } dvi_buf | 109 \rangle \equiv$ if  $dvi\_limit = half\_buf$  then  $write\_dvi(half\_buf, dvi\_buf\_size - 1)$ ; if  $dvi_ptr > 0$  then  $write_dvi(0, dvi_ptr - 1)$ 

This code is used in section 115.

The *dvi\_four* procedure outputs four bytes in two's complement notation, without risking arithmetic 110. overflow.

**procedure**  $dvi_four(x:integer);$ begin if x > 0 then  $dvi_out(x \operatorname{div} 100000000)$ else begin  $x \leftarrow x + (10000000000); x \leftarrow x + (10000000000); dvi_out((x \operatorname{div} (100000000)) + 128);$ end;  $x \leftarrow x \mod (100000000; dv_iout(x \operatorname{div} (200000); x \leftarrow x \mod (200000); dv_iout(x \operatorname{div} (400);$  $dvi_out(x \mod 400);$ end;

Here's a procedure that outputs a font definition. 111.

**define** select\_font(#)  $\equiv$  dvi\_out(fnt\_num\_0 + #) { set current font to # }

**procedure** *dvi\_font\_def* (*f* : *internal\_font\_number*); **var** k: integer; { index into str\_pool } **begin**  $dvi_out(fnt_def1)$ ;  $dvi_out(f)$ ;  $dvi_out(qo(font\_check[f].b0)); dvi_out(qo(font\_check[f].b1)); dvi_out(qo(font\_check[f].b2));$  $dvi_out(qo(font_check[f].b3));$ dvi\_four(font\_size[f]); dvi\_four(font\_dsize[f]); dvi\_out(length(font\_area[f])); dvi\_out(length(font\_name[f])); (Output the font name whose internal number is  $f_{112}$ ); end:

 $\langle \text{Declare the procedure called } load_fonts 98 \rangle$ 

112. (Output the font name whose internal number is  $f_{112} \equiv$ for  $k \leftarrow str_start[font_area[f]]$  to  $str_start[font_area[f] + 1] - 1$  do  $dvi_out(str_pool[k]);$ for  $k \leftarrow str\_start[font\_name[f]]$  to  $str\_start[font\_name[f]+1] - 1$  do  $dvi\_out(str\_pool[k])$ 

This code is used in section 111.

113. The *typeset* subroutine typesets any eight-bit character.

```
procedure typeset(c: eight_bits);

begin if c \ge 128 then dvi_out(set1);

dvi_out(c);

end;
```

**114.** The *dvi\_scaled* subroutine takes a *real* value x and outputs a decimal approximation to x/unity, correct to one decimal place.

```
procedure dvi\_scaled(x : real);
  var n: integer; { an integer approximation to 10 * x/unity }
     m: integer; { the integer part of the answer }
     k: integer; { the number of digits in m }
  begin n \leftarrow round(x/6553.6);
  if n < 0 then
     begin dvi_out("-"); n \leftarrow -n;
     end:
  m \leftarrow n \operatorname{\mathbf{div}} 10; k \leftarrow 0;
  repeat incr(k); buffer[k] \leftarrow (m \mod 10) + "0"; m \leftarrow m \operatorname{div} 10;
  until m = 0;
  repeat dvi_out(buffer[k]); decr(k);
  until k = 0;
  if n \mod 10 \neq 0 then
     begin dvi_out("."); dvi_out((n \mod 10) + "0");
     end:
  end:
```

**115.** At the end of the program, we must finish things off by writing the postamble. An integer variable k will be declared for use by this routine.

```
\langle Finish the DVI file and goto final_end 115\rangle \equiv
  begin dvi_out(post); { beginning of the postamble }
  dvi_four(last_bop); \ last_bop \leftarrow dvi_offset + dvi_ptr - 5;
                                                                 { post location }
  dvi_{four}(25400000); dvi_{four}(473628672); \{ conversion ratio for sp \}
  dvi_four(1000); { magnification factor }
  dvi_four(max_v); dvi_four(max_h);
  dvi_out(0); dvi_out(3); \{ max_push' \text{ is said to be } 3 \}
  dvi_out(total_pages div 256); dvi_out(total_pages mod 256);
  if ¬fonts_not_loaded then
     for k \leftarrow title_font to logo_font do
       if length(font_name[k]) > 0 then dvi_font_def(k);
  dvi_out(post_post); dvi_four(last_bop); dvi_out(dvi_id_byte);
  k \leftarrow 4 + ((dvi_buf_size - dvi_ptr) \mod 4); \ \{\text{the number of } 223\text{'s}\}
  while k > 0 do
     begin dvi_out(223); decr(k);
     end:
  \langle Empty the last bytes out of dvi_buf 109 \rangle;
  goto final_end;
  end
This code is used in section 219.
```

GF to DVI §116

116. Rudimentary typesetting. One of GFtoDVI's little duties is to be a mini- $T_EX$ : It must be able to typeset the equivalent of '\hbox{ $string}$ ' for a given string of ASCII characters, using either the title font or the label font.

The *hbox* procedure does this. The width, height, and depth of the box defined by string s in font f are computed in global variables *box\_width*, *box\_height*, and *box\_depth*.

The task would be trivial if it weren't for ligatures and kerns, which are implemented here in full generality. (Infinite looping is possible if the TFM file is malformed; TFtoPL will diagnose such problems.)

We assume that " $_{\Box}$ " is a space character; character code '40 will not be typeset unless it is accessed via a ligature.

If parameter  $send_it$  is false, we merely want to know the box dimensions. Otherwise typesetting commands are also sent to the DVI file; we assume in this case that font f has already been selected in the DVI file as the current font.

```
define set_cur_r \equiv
            if k < end_k then cur_r \leftarrow qi(str_pool[k])
            else cur_r \leftarrow bchar
procedure hbox(s : str_number; f : internal_font_number; send_it : boolean);
  label continue, done;
  var k, end_k, max_k: pool_pointer; { indices into str_pool }
     i, j: four_quarters; { font information words }
     cur_l: 0...256; { character to the left of the "cursor" }
     cur_r: min_quarterword .. non_char; { character to the right of the "cursor" }
     bchar: min_quarterword ... non_char; { right boundary character }
     stack_ptr: 0.. lig_lookahead; { number of entries on lig_stack }
     l: font_index; { pointer to lig/kern instruction }
     kern_amount: scaled; { extra space to be typeset }
     hd: eight_bits; { height and depth indices for a character }
     x: scaled; { temporary register }
     save_c: ASCII_code; { character temporarily blanked out }
  begin box_width \leftarrow 0; box_height \leftarrow 0; box_depth \leftarrow 0;
  k \leftarrow str\_start[s]; max_k \leftarrow str\_start[s+1]; save_c \leftarrow str\_pool[max_k]; str\_pool[max_k] \leftarrow "_u";
  while k < max_k do
     begin if str_{pool}[k] = " " then \langle Typeset a space in font f and advance k 119 \rangle
     else begin end_k \leftarrow k;
       repeat incr(end_k);
       until str_pool[end_k] = "_{\downarrow\downarrow}";
       kern\_amount \leftarrow 0; \ cur\_l \leftarrow 256; \ stack\_ptr \leftarrow 0; \ bchar \leftarrow font\_bchar[f]; \ set\_cur\_r;
       suppress\_liq \leftarrow false;
     continue: (If there's a ligature or kern at the cursor position, update the cursor data structures,
            possibly advancing k; continue until the cursor wants to move right 120;
       (Typeset character cur_l, if it exists in the font; also append an optional kern 121);
       (Move the cursor to the right and goto continue, if there's more work to do in the current word 123);
       end; { now k = end_k }
     end:
  str_pool[max_k] \leftarrow save_c;
  end:
```

**117.**  $\langle$  Globals in the outer block  $|2\rangle +\equiv$ box\_width: scaled; { width of box constructed by hbox } box\_height: scaled; { height of box constructed by hbox } box\_depth: scaled; { depth of box constructed by hbox } lig\_stack: **array** [1.. lig\_lookahead] **of** quarterword; { inserted ligature chars } dummy\_info: four\_quarters; { fake char\_info for nonexistent character } suppress\_lig: boolean; { should we bypass checking for ligatures next time? }

**118.** (Set initial values 13) +=  $dummy_info.b0 \leftarrow qi(0); dummy_info.b1 \leftarrow qi(0); dummy_info.b2 \leftarrow qi(0); dummy_info.b3 \leftarrow qi(0);$ 

```
119. (Typeset a space in font f and advance k 119) =
begin box_width ← box_width + space(f);
if send_it then
    begin dvi_out(right4); dvi_four(space(f));
    end;
    incr(k);
end
```

This code is used in section 116.

120. (If there's a ligature or kern at the cursor position, update the cursor data structures, possibly advancing k; continue until the cursor wants to move right 120 )  $\equiv$ 

```
if (cur_l < font_bc[f]) \lor (cur_l > font_ec[f]) then
  begin i \leftarrow dummy\_info;
  if cur_l = 256 then l \leftarrow bchar_label[f] else l \leftarrow non_address;
  end
else begin i \leftarrow char\_info(f)(cur\_l);
  if char_taq(i) \neq liq_taq then l \leftarrow non_address
  else begin l \leftarrow lig\_kern\_start(f)(i); j \leftarrow font\_info[l].qqqq;
     if skip_byte(j) > stop_flag then l \leftarrow lig_kern_restart(f)(j);
     end;
  end:

This code is used in section 116.

124. Gray fonts. A proof diagram constructed by GFtoDVI can be regarded as an array of rectangles, where each rectangle is either blank or filled with a special symbol that we shall call x. A blank rectangle represents a white pixel, while x represents a black pixel. Additional labels and reference lines are often superimposed on this array of rectangles; hence it is usually best to choose a symbol x that has a somewhat gray appearance, although any symbol can actually be used.

In order to construct such proofs, GFtoDVI needs to work with a special type of font known as a "gray font"; it's possible to obtain a wide variety of different sorts of proofs by using different sorts of gray fonts. The next few paragraphs explain exactly what gray fonts are supposed to contain, in case you want to design your own.

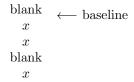

125. The simplest gray font contains only two characters, namely x and another symbol that is used for dots that identify key points. If proofs with relatively large pixels are desired, a two-character gray font is all that's needed. However, if the pixel size is to be relatively small, practical considerations make a two-character font too inefficient, since it requires the typesetting of tens of thousands of tiny little characters; printing device drivers rarely work very well when they are presented with data that is so different from ordinary text. Therefore a gray font with small pixels usually has a number of characters that replicate x in such a way that comparatively few characters actually need to be typeset.

Since many printing devices are not able to cope with arbitrarily large or complex characters, it is not possible for a single gray font to work well on all machines. In fact, x must have a width that is an integer multiple of the printing device's unit of horizontal position, since rounding the positions of grey characters would otherwise produce unsightly streaks on proof output. Thus, there is no way to make the gray font as device-independent as the rest of the system, in the sense that we would expect approximately identical output on machines with different resolution. Fortunately, proof sheets are rarely considered to be final documents; hence **GFtoDVI** is set up to provide results that adapt suitably to local conditions.

126. With such constraints understood, we can now take a look at what GFtoDVI expects to see in a gray font. The character x always appears in position 1. It must have positive height h and positive width w; its depth and italic correction are ignored.

Positions 2–120 of a gray font are reserved for special combinations of x's and blanks, stacked on top of each other. None of these character codes need be present in the font; but if they are, the slots should be occupied by characters of width w that have certain configurations of x's and blanks, prescribed for each character position. For example, position 3 of the font should either contain no character at all, or it should contain a character consisting of two x's, one above the other; one of these x's should appear immediately above the baseline, and the other should appear immediately below.

It will be convenient to use a horizontal notation like 'XOXXO' to stand for a vertical stack of x's and blanks. The convention will be that the stack is built from bottom to top, and the topmost rectangle should sit on the baseline. Thus, 'XOXXO' stands actually for a character of depth 4h that looks like this:

(We use a horizontal notation instead of a vertical one in this explanation, because column vectors take too much space, and because the horizontal notation corresponds to binary numbers in a convenient way.)

Positions 1–63 of a gray font are reserved for the patterns X, XO, XX, XOO, XOX, ..., XXXXXX, just as in the normal binary notation of the numbers 1–63. Positions 64–70 are reserved for the special patterns X000000, XX00000, ..., XXXXXX0, XXXXXXX of length seven; positions 71–78 are, similarly, reserved for the length-eight patterns X0000000 through XXXXXXXXX. The length-nine patterns X0000000 through XXXXXXXX are assigned to positions 79–87, the length-ten patterns to positions 88–97, the length-eleven patterns to positions 98–108, and the length-twelve patterns to positions 109–120.

The following program sets a global array c[1 ... 120] to the bit patterns just described. Another array d[1 ... 120] is set to contain only the next higher bit; this determines the depth of the corresponding character. (Set initial values 13)  $+\equiv$ 

 $c[1] \leftarrow 1; \ d[1] \leftarrow 2; \ two\_to\_the[0] \leftarrow 1; \ m \leftarrow 1;$ for  $k \leftarrow 1$  to 13 do  $two\_to\_the[k] \leftarrow 2 * two\_to\_the[k-1];$ for  $k \leftarrow 2$  to 6 do  $\langle$  Add a full set of k-bit characters 128 $\rangle$ ; for  $k \leftarrow 7$  to 12 do  $\langle$  Add special k-bit characters of the form X..XO..O 129 $\rangle$ ;

**127.**  $\langle$  Globals in the outer block  $12 \rangle +\equiv$ c: **array** [1..120] **of** 1..4095; { bit patterns for a gray font } d: **array** [1..120] **of** 2..4096; { the superleading bits } two\_to\_the: **array** [0..13] **of** 1..8192; { powers of 2 }

```
128. \langle \text{Add a full set of } k\text{-bit characters } 128 \rangle \equiv 

begin n \leftarrow two\_to\_the[k-1];

for j \leftarrow 0 to n-1 do

begin incr(m); c[m] \leftarrow m; d[m] \leftarrow n+n;

end;

end
```

This code is used in section 126.

**129.**  $\langle \text{Add special } k\text{-bit characters of the form } X..X0..0 | 129 \rangle \equiv$  **begin**  $n \leftarrow two\_to\_the[k-1];$  **for**  $j \leftarrow k$  **downto** 1 **do begin**  $incr(m); d[m] \leftarrow n + n;$  **if** j = k **then**  $c[m] \leftarrow n$  **else**  $c[m] \leftarrow c[m-1] + two\_to\_the[j-1];$  **end**; **end** 

This code is used in section 126.

130. Position 0 of a gray font is reserved for the "dot" character, which should have positive height h' and positive width w'. When GFtoDVI wants to put a dot at some place (x, y) on the figure, it positions the dot character so that its reference point is at (x, y). The dot will be considered to occupy a rectangle  $(x + \delta, y + \epsilon)$  for  $-w' \le \delta \le w'$  and  $-h' \le \epsilon \le h'$ ; the rectangular box for a label will butt up against the rectangle enclosing the dot.

131. All other character positions of a gray font (namely, positions 121–255) are unreserved, in the sense that they have no predefined meaning. But GFtoDVI may access them via the "character list" feature of TFM files, starting with any of the characters in positions 1–120. In such a case each succeeding character in a list should be equivalent to two of its predecessors, horizontally adjacent to each other. For example, in a character list like

### 53, 121, 122, 123

character 121 will stand for two 53's, character 122 for two 121's (i.e., four 53's), and character 123 for two 122's (i.e., eight 53's). Since position 53 contains the pattern XXOXOX, character 123 in this example would have height h, depth 5h, and width 8w, and it would stand for the pattern

Such a pattern is, of course, rather unlikely to occur in a GF file, but GFtoDVI would be able to use if it were present. Designers of gray fonts should provide characters only for patterns that they think will occur often enough to make the doubling worthwhile. For example, the character in position 120 (XXXXXXXXXXX), or whatever is the tallest stack of x's present in the font, is a natural candidate for repeated doubling.

Here's how GFtoDVI decides what characters of the gray font will be used, given a configuration of black and white pixels: If there are no black pixels, stop. Otherwise look at the top row that contains at least one black pixel, and the eleven rows that follow. For each such column, find the largest k such that  $1 \le k \le 120$ and the gray font contains character k and the pattern assigned to position k appears in the given column. Typeset character k (unless no such character exists) and erase the corresponding black pixels; use doubled characters, if they are present in the gray font, if two or more consecutive equal characters need to be typeset. Repeat the same process on the remaining configuration, until all the black pixels have been erased.

If all characters in positions 1-120 are present, this process is guaranteed to take care of at least six rows each time; and it usually takes care of twelve, since all patterns that contain at most one "run" of x's are present.

**132.** Fonts have optional parameters, as described in Appendix F of The  $T_EXbook$ , and some of these are important in gray fonts. The slant parameter s, if nonzero, will cause GFtoDVI to skew its output; in this case the character x will presumably be a parallelogram with a corresponding slant, rather than the usual rectangle. METAFONT's coordinate (x, y) will appear in physical position (xw + yhs, yh) on the proofsheets.

Parameter number 8 of a gray font specifies the thickness of rules that go on the proofs. If this parameter is zero,  $T_EX$ 's default rule thickness (0.4 pt) will be used.

The other parameters of a gray font are ignored by GFtoDVI, but it is conventional to set the font space parameter to w and the xheight parameter to h.

133. For best results the designer of a gray font should choose h and w so that the user's DVI-to-hardcopy software will not make any rounding errors. Furthermore, the dot should be an even number 2m of pixels in diameter, and the rule thickness should work out to an even number 2n of pixels; then the dots and rules will be centered on the correct positions, in case of integer coordinates. Gray fonts are almost always intended for particular output devices, even though 'DVI' stands for 'device independent'; we use DVI files for METAFONT proofs chiefly because software to print DVI files is already in place.

134. Slant fonts. GFtoDVI also makes use of another special type of font, if it is necessary to typeset slanted rules. The format of such so-called "slant fonts" is quite a bit simpler than the format of gray fonts. A slant font should contain exactly n characters, in positions 1 to n, where the character in position k

represents a slanted line k units tall, starting at the baseline. These lines all have a fixed slant ratio s. The following simple algorithm is used to typeset a rule that is m units high: Compute  $q = \lceil m/n \rceil$ ; then typeset q characters of approximately equal size, namely  $(m \mod q)$  copies of character number  $\lceil m/q \rceil$  and  $q - (m \mod q)$  copies of character number  $\lfloor m/q \rfloor$ . For example, if n = 15 and m = 100, we have q = 7; a 100-unit-high rule will be composed of 7 pieces, using characters 14, 14, 14, 14, 14, 15, 15.

 $\langle$  Globals in the outer block 12  $\rangle +\equiv$ 

*rule\_slant*: *real*; { the slant ratio s in the slant font, or zero if there is no slant font }

slant\_n: integer; { the number of characters in the slant font }

*slant\_unit*: *real*; { the number of scaled points in the slant font unit }

*slant\_reported*: *real*; { invalid slant ratio reported to the user }

**135.** GFtoDVI looks only at the height of character n, so the TFM file need not be accurate about the heights of the other characters. (This is fortunate, since TFM format allows at most 16 different heights per font.)

The width of character k should be k/n times s times the height of character n.

The slant parameter of a slant file should be s. It is customary to set the  $default\_rule\_thickness$  parameter (number 8) to the thickness of the slanted rules, but GFtoDVI doesn't look at it.

**136.** For best results on a particular output device, it is usually wise to choose the 'unit' in the above discussion to be an integer number of pixels, and to make it no larger than the default rule thickness in the gray font being used.

137. (Initialize global variables that depend on the font data 137)  $\equiv$ 

if  $length(font\_name[slant\_font]) = 0$  then  $rule\_slant \leftarrow 0.0$ 

else begin  $rule\_slant \leftarrow slant(slant\_font)/unity; slant\_n \leftarrow font\_ec[slant\_font];$   $i \leftarrow char\_info(slant\_font)(slant\_n); slant\_unit \leftarrow char\_height(slant\_font)(height\_depth(i))/slant\_n;$ end;  $slant\_reported \leftarrow 0.0;$ 

See also sections 169, 175, 184, 205, and 206.

This code is used in section 98.

138. The following error message is given when an absent slant has been requested.

```
procedure slant_complaint(r : real);
```

```
begin if abs(r - slant_reported) > 0.001 then
    begin print_nl(`Sorry, ⊔I⊔can´`t⊔make⊔diagonal⊔rules⊔of⊔slant⊔`, r : 10 : 5, `!`);
    slant_reported ← r;
    end;
end;
```

#### §139 GF to DVI

**139.** Representation of rectangles. OK—the preliminary spadework has now been done. We're ready at last to concentrate on GFtoDVI's raison d'être.

One of the most interesting tasks remaining is to make a "map" of the labels that have been allocated. There usually aren't a great many labels, so we don't need fancy data structures; but we do make use of linked nodes containing nine fields. The nodes generally represent rectangular boxes according to the following conventions:

- xl, xr, yt, and yb are the left, right, top, and bottom locations of a rectangle, expressed in DVI coordinates. (This program uses scaled points as DVI coordinates. Since DVI coordinates increase as one moves down the page, yb will be greater than yt.)
- xx and yy are the coordinates of the reference point of a box to be typeset from this node, again in DVI coordinates.
- prev and next point to the predecessor and successor of this node. Sometimes the nodes are singly linked and only next is relevant; otherwise the nodes are doubly linked in order of their yy coordinates, so that we can move down by going to next, or up by going to prev.

info is the number of a string associated with this node.

The nine fields of a node appear in nine global arrays. Null pointers are denoted by null, which happens to be zero.

define null = 0

 $\langle \text{Types in the outer block } 9 \rangle + \equiv$ node\_pointer = null ... max\_labels;

**140.**  $\langle$  Globals in the outer block 12 $\rangle +\equiv xl, xr, yt, yb$ : **array**  $[1 \dots max\_labels]$  **of** scaled; { boundary coordinates } xx, yy: **array**  $[0 \dots max\_labels]$  **of** scaled; { reference coordinates } prev, next: **array**  $[0 \dots max\_labels]$  **of** node\\_pointer; { links } info: **array**  $[1 \dots max\_labels]$  **of** str\\_number; { associated strings } max\\_node: node\\_pointer; { the largest node in use } max\\_height: scaled; { greatest difference between yy and yt } max\\_depth: scaled; { greatest difference between yb and yy }

141. It's easy to allocate a new node (unless no more room is left):

```
function get_avail: node_pointer;
begin incr(max_node);
if max_node = max_labels then abort(~Too∟many⊔labels⊔and/or⊔rules!~);
get_avail ← max_node;
end;
```

142. The doubly linked nodes are sorted by yy coordinates so that we don't have to work too hard to find nearest neighbors or to determine if rectangles overlap. The first node in the doubly linked rectangle list is always in location 0, and the last node is always in location  $max\_labels$ ; the yy coordinates of these nodes are very small and very large, respectively.

**define**  $end_of_list \equiv max_labels$ 

 $\begin{array}{l} \langle \text{ Set initial values } 13 \rangle + \equiv \\ yy[0] \leftarrow -10000000000; \ yy[end\_of\_list] \leftarrow 10000000000; \end{array}$ 

143. The *node\_ins* procedure inserts a new rectangle, represented by node p, into the doubly linked list. There's a second parameter, q; node q should already be in the doubly linked list, preferably with yy[q] near yy[p].

procedure node\_ins(p,q:node\_pointer); var r: node\_pointer; { for tree traversal } begin if  $yy[p] \ge yy[q]$  then begin repeat  $r \leftarrow q$ ;  $q \leftarrow next[q]$ ; until  $yy[p] \le yy[q]$ ;  $next[r] \leftarrow p$ ;  $prev[p] \leftarrow r$ ;  $next[p] \leftarrow q$ ;  $prev[q] \leftarrow p$ ; end else begin repeat  $r \leftarrow q$ ;  $q \leftarrow prev[q]$ ; until  $yy[p] \ge yy[q]$ ;  $prev[r] \leftarrow p$ ;  $next[p] \leftarrow r$ ;  $prev[p] \leftarrow q$ ;  $next[q] \leftarrow p$ ; end; if  $yy[p] - yt[p] > max_height$  then  $max_height \leftarrow yy[p] - yt[p]$ ; if  $yb[p] - yy[p] > max_depth$  then  $max_depth \leftarrow yb[p] - yy[p]$ ; end;

144. The data structures need to be initialized for each character in the GF file.

 $\langle$  Initialize variables for the next character 144 $\rangle \equiv$ 

 $max\_node \leftarrow 0; next[0] \leftarrow end\_of\_list; prev[end\_of\_list] \leftarrow 0; max\_height \leftarrow 0; max\_depth \leftarrow 0;$ See also sections 156 and 161.

This code is used in section 219.

145. The overlap subroutine determines whether or not the rectangle specified in node p has a nonempty intersection with some rectangle in the doubly linked list. Again q is a parameter that gives us a starting point in the list. We assume that  $q \neq end_of_list$ , so that next[q] is meaningful.

function  $overlap(p, q: node_pointer)$ : boolean;label exit;var  $y\_thresh: scaled;$  { cutoff value to speed the search }  $x\_left, x\_right, y\_top, y\_bot: scaled;$  { boundaries to test for overlap }  $r: node\_pointer;$  { runs through the neighbors of q } begin  $x\_left \leftarrow xl[p]; x\_right \leftarrow xr[p]; y\_top \leftarrow yt[p]; y\_bot \leftarrow yb[p];$   $\langle Look for overlaps in the successors of node <math>q$  146  $\rangle;$   $\langle Look for overlaps in node <math>q$  and its predecessors 147  $\rangle;$   $overlap \leftarrow false;$ exit: end;

```
146. \langle \text{Look for overlaps in the successors of node } q \text{ 146} \rangle \equiv y\_thresh \leftarrow y\_bot + max\_height; r \leftarrow next[q];

while yy[r] < y\_thresh do

begin if y\_bot > yt[r] then

if x\_left < xr[r] then

if x\_right > xl[r] then

if y\_top < yb[r] then

begin overlap \leftarrow true; return;

end;

r \leftarrow next[r];

end
```

This code is used in section 145.

147.  $\langle \text{Look for overlaps in node } q \text{ and its predecessors } 147 \rangle \equiv y\_thresh \leftarrow y\_top - max\_depth; r \leftarrow q;$ while  $yy[r] > y\_thresh$  do begin if  $y\_bot > yt[r]$  then if  $x\_left < xr[r]$  then if  $x\_right > xl[r]$  then if  $y\_top < yb[r]$  then begin  $overlap \leftarrow true;$  return; end;  $r \leftarrow prev[r];$ end

This code is used in section 145.

148. Nodes that represent dots instead of labels satisfy the following constraints:

info[p] < 0;	$p \ge first\_dot;$
$xl[p] = xx[p] - dot_width,$	$xr[p] = xx[p] + dot_width;$
$yt[p] = yy[p] - dot_height,$	$yb[p] = yy[p] + dot_height.$

The *nearest\_dot* subroutine finds a node whose reference point is as close as possible to a given position, ignoring nodes that are too close. More precisely, the "nearest" node minimizes

$$d(q,p) = \max(|xx[q] - xx[p]|, |yy[q] - yy[p]|)$$

over all nodes q with  $d(q,p) \ge d\theta$ . We call the subroutine *nearest\_dot* because it is used only when the doubly linked list contains nothing but dots.

The routine also sets the global variable *twin* to *true*, if there is a node  $q \neq p$  with  $d(q, p) < d\theta$ .

**149.**  $\langle$  Globals in the outer block  $12 \rangle +\equiv$ first\_dot: node\_pointer; { the node address where dots begin } twin: boolean; { is there a nearer dot than the "nearest" dot? }

150. If there is no nearest dot, the value *null* is returned; otherwise a pointer to the nearest dot is returned.

function nearest\_dot(p: node\_pointer; d0 : scaled): node\_pointer; var best\_q: node\_pointer; { value to return }  $d_{min}, d:$  scaled; { distances } begin twin  $\leftarrow$  false; best\_q  $\leftarrow$  0;  $d_{min} \leftarrow$  '2000000000;  $\langle$  Search for the nearest dot in nodes following p 151  $\rangle$ ;  $\langle$  Search for the nearest dot in nodes preceding p 152  $\rangle$ ; nearest\_dot  $\leftarrow$  best\_q; end; **151.**  $\langle$  Search for the nearest dot in nodes following  $p | 151 \rangle \equiv q \leftarrow next[p];$ while  $yy[q] < yy[p] + d_min$  do begin  $d \leftarrow abs(xx[q] - xx[p]);$ if d < yy[q] - yy[p] then  $d \leftarrow yy[q] - yy[p];$ if d < d0 then  $twin \leftarrow true$ else if  $d < d_min$  then begin  $d_min \leftarrow d; best_q \leftarrow q;$ end;  $q \leftarrow next[q];$ end

This code is used in section 150.

**152.**  $\langle$  Search for the nearest dot in nodes preceding  $p | 152 \rangle \equiv q \leftarrow prev[p];$ while  $yy[q] > yy[p] - d\_min$  do begin  $d \leftarrow abs(xx[q] - xx[p]);$ if d < yy[p] - yy[q] then  $d \leftarrow yy[p] - yy[q];$ if d < d0 then  $twin \leftarrow true$ else if  $d < d\_min$  then begin  $d\_min \leftarrow d; best\_q \leftarrow q;$ end;  $q \leftarrow prev[q];$ end

This code is used in section 150.

**153.** Doing the labels. Each "character" in the GF file is preceded by a number of special commands that define labels, titles, rules, etc. We store these away, to be considered later when the *boc* command appears. The *boc* command establishes the size information by which labels and rules can be positioned, so we spew out the label information as soon as we see the *boc*. The gray pixels will be typeset after all the labels for a particular character have been finished.

154. Here is the part of GFtoDVI that stores information preceding a *boc*. It comes into play when  $cur_gf$  is between xxx1 and  $no_op$ , inclusive.

```
define font_change(\#) \equiv
             if fonts_not_loaded then
                 begin #;
                 end
             else print_nl(`(Tardy_font_change_will_be_ignored_(byte_`, cur_loc:1, `)!)`)
\langle \text{Process a no-op command } 154 \rangle \equiv
  begin k \leftarrow interpret\_xxx;
  case k of
  no_operation: do_nothing;
  title_font, label_font, gray_font, slant_font: font_change(font_name[k] \leftarrow cur_string;
           font\_area[k] \leftarrow null\_string; font\_at[k] \leftarrow 0; init\_str\_ptr \leftarrow str\_ptr);
  title\_font + area\_code, label\_font + area\_code, gray\_font + area\_code, slant\_font + area\_code:
           font\_change(font\_area[k - area\_code] \leftarrow cur\_string; init\_str\_ptr \leftarrow str\_ptr);
  title\_font + at\_code, label\_font + at\_code, gray\_font + at\_code, slant\_font + at\_code:
           font\_change(font\_at|k - at\_code] \leftarrow get\_yyy; init\_str\_ptr \leftarrow str\_ptr);
  rule\_thickness\_code: rule\_thickness \leftarrow get\_yyy;
  rule_code: \langle Store a rule 159\rangle;
  offset_code: \langle \text{Override the offsets } 157 \rangle;
  x_offset\_code: x_offset \leftarrow get_yyy;
  y_{offset\_code: y_{offset} \leftarrow get_{yyy};
  title_code: \langle Store a title 162\rangle;
  null_string: \langle Store a label 163 \rangle;
  end; { there are no other cases }
  end
```

This code is used in section 219.

**155.** The following quantities are cleared just before reading the GF commands pertaining to a character. (Globals in the outer block 12) += rule\_thickness: scaled; { the current rule thickness (zero means use the default) } offset\_x, offset\_y: scaled; { the current offsets for images }

 $x_offset, y_offset: scaled; \{ the current offsets for labels \}$ 

pre\_min\_x, pre\_max\_x, pre\_min\_y, pre\_max\_y: scaled;

{extreme values of coordinates preceding a character, in METAFONT pixels}

**156.** (Initialize variables for the next character 144)  $+\equiv$ rule\_thickness  $\leftarrow 0$ ; offset\_x  $\leftarrow 0$ ; offset\_y  $\leftarrow 0$ ; x\_offset  $\leftarrow 0$ ; y\_offset  $\leftarrow 0$ ; pre\_min\_x  $\leftarrow 2000000000$ ; pre\_max\_x  $\leftarrow -2000000000$ ; pre\_min\_y  $\leftarrow 2000000000$ ; pre\_max\_y  $\leftarrow -20000000000$ ;

**157.**  $\langle \text{Override the offsets } 157 \rangle \equiv$ **begin** *offset\_x*  $\leftarrow$  *get\_yyy*; *offset\_y*  $\leftarrow$  *get\_yyy*; **end** 

This code is used in section 154.

**158.** Rules that will need to be drawn are kept in a linked list accessible via *rule\_ptr*, in last-in-first-out order. The nodes of this list will never get into the doubly linked list, and indeed these nodes use different field conventions entirely (because rules may be slanted).

**define**  $x0 \equiv xl$  { starting x coordinate of a stored rule } **define**  $y0 \equiv yt$  { starting y coordinate (in scaled METAFONT pixels) } **define**  $x1 \equiv xr$  { ending x coordinate of a stored rule } **define**  $y1 \equiv yb$  { ending y coordinate of a stored rule } **define**  $rule\_size \equiv xx$  { thickness of a stored rule, in scaled points }

 $\langle$  Globals in the outer block  $12\,\rangle$  +=

rule\_ptr: node\_pointer; { top of the stack of remembered rules }

## **159.** $\langle$ Store a rule $159 \rangle \equiv$

 $\begin{array}{l} \mathbf{begin} \ p \leftarrow get\_avail; \ next[p] \leftarrow rule\_ptr; \ rule\_ptr \leftarrow p; \\ x0[p] \leftarrow get\_yyy; \ y0[p] \leftarrow get\_yyy; \ x1[p] \leftarrow get\_yyy; \ y1[p] \leftarrow get\_yyy; \\ \mathbf{if} \ x0[p] < pre\_min\_x \ \mathbf{then} \ pre\_min\_x \leftarrow x0[p]; \\ \mathbf{if} \ x0[p] > pre\_max\_x \ \mathbf{then} \ pre\_max\_x \leftarrow x0[p]; \\ \mathbf{if} \ y0[p] < pre\_min\_y \ \mathbf{then} \ pre\_max\_y \leftarrow y0[p]; \\ \mathbf{if} \ y0[p] > pre\_max\_y \ \mathbf{then} \ pre\_max\_y \leftarrow y0[p]; \\ \mathbf{if} \ x1[p] < pre\_min\_x \ \mathbf{then} \ pre\_max\_x \leftarrow x1[p]; \\ \mathbf{if} \ x1[p] > pre\_max\_x \ \mathbf{then} \ pre\_max\_x \leftarrow x1[p]; \\ \mathbf{if} \ y1[p] < pre\_min\_y \ \mathbf{then} \ pre\_max\_x \leftarrow y1[p]; \\ \mathbf{if} \ y1[p] > pre\_max\_y \ \mathbf{then} \ pre\_max\_y \leftarrow y1[p]; \\ \mathbf{if} \ y1[p] > pre\_max\_y \ \mathbf{then} \ pre\_max\_y \leftarrow y1[p]; \\ \mathbf{rule\_size}[p] \leftarrow rule\_thickness; \\ \mathbf{end} \end{array}$ 

This code is used in section 154.

160. Titles and labels are, likewise, stored temporarily in singly linked lists. In this case the lists are first-in-first-out. Variables *title\_tail* and *label\_tail* point to the most recently inserted title or label; variables *title\_head* and *label\_head* point to the beginning of the list. (A standard coding trick is used for *label\_head*, which is kept in  $next[end_of_list]$ ; we have  $label_tail = end_of_list$  when the list is empty.)

The prev field in nodes of the temporary label list specifies the type of label, so we call it *lab\_typ*.

**define**  $lab\_typ \equiv prev$  { the type of a stored label ("/" ... "8") } **define**  $label\_head \equiv next[end\_of\_list]$ 

 $\langle \text{Globals in the outer block } 12 \rangle + \equiv$ 

label\_tail: node\_pointer; { tail of the queue of remembered labels }
title\_head, title\_tail: node\_pointer; { head and tail of the queue for titles }

**161.** We must start the lists out empty.

 $\langle \text{Initialize variables for the next character } 144 \rangle + \equiv$   $rule\_ptr \leftarrow null; title\_head \leftarrow null; title\_tail \leftarrow null; label\_head \leftarrow null; label\_tail \leftarrow end\_of\_list;$  $first\_dot \leftarrow max\_labels;$ 

```
162. (Store a title 162) \equiv

begin p \leftarrow get\_avail; info[p] \leftarrow cur\_string;

if title\_head = null then title\_head \leftarrow p

else next[title\_tail] \leftarrow p;

title\_tail \leftarrow p;

end
```

This code is used in section 154.

**163.** We store the coordinates of each label in units of METAFONT pixels; they will be converted to DVI coordinates later.

 $\langle \text{Store a label 163} \rangle \equiv \\ \text{if } (label\_type < "/") \lor (label\_type > "8") \text{ then } \\ print\_nl(`Bad\_label\_type\_precedes\_byte\_`, cur\_loc: 1, `!`) \\ \text{else begin } p \leftarrow get\_avail; next[label\_tail] \leftarrow p; label\_tail \leftarrow p; \\ lab\_typ[p] \leftarrow label\_type; info[p] \leftarrow cur\_string; \\ xx[p] \leftarrow get\_yyy; yy[p] \leftarrow get\_yyy; \\ \text{if } xx[p] < pre\_min\_x \text{ then } pre\_min\_x \leftarrow xx[p]; \\ \text{if } xx[p] > pre\_max\_x \text{ then } pre\_max\_x \leftarrow xx[p]; \\ \text{if } yy[p] < pre\_min\_y \text{ then } pre\_min\_y \leftarrow yy[p]; \\ \text{if } yy[p] > pre\_max\_y \text{ then } pre\_max\_y \leftarrow yy[p]; \\ \text{end} \\ \end{cases}$ 

This code is used in section 154.

**164.** The process of ferreting everything away comes to an abrupt halt when a *boc* command is sensed. The following steps are performed at such times:

 $\langle \text{Process a character 164} \rangle \equiv \\ \text{begin check_fonts; } \langle \text{Finish reading the parameters of the boc 165} \rangle; \\ \langle \text{Get ready to convert METAFONT coordinates to DVI coordinates 170} \rangle; \\ \langle \text{Output the bop and the title line 172} \rangle; \\ print(`[`, total_pages : 1); update_terminal; { print a progress report } \\ \langle \text{Output all rules for the current character 173} \rangle; \\ \langle \text{Output all labels for the current character 181}; \\ do_pixels; dvi_out(eop); { finish the page } \\ \langle \text{Adjust the maximum page width 203} \rangle; \\ print(`]`); update_terminal; \\ end \\ \end{cases}$ 

This code is used in section 219.

165.  $\langle$  Finish reading the parameters of the *boc* 165  $\rangle \equiv$ if  $cur_qf = boc$  then **begin**  $ext \leftarrow signed_quad; \{ read the character code \}$  $char\_code \leftarrow ext \mod 256;$ if  $char_code < 0$  then  $char_code \leftarrow char_code + 256$ ;  $ext \leftarrow (ext - char_code)$  div 256;  $k \leftarrow signed_quad$ ; {read and ignore the prev pointer}  $min_x \leftarrow signed_quad; \{ read the minimum x coordinate \}$  $max_x \leftarrow signed_quad;$  $\{ read the maximum x coordinate \}$  $min_y \leftarrow signed_quad; \{ read the minimum y coordinate \}$  $max_y \leftarrow signed_quad; \{ read the maximum y coordinate \}$ end else begin  $ext \leftarrow 0$ ;  $char_code \leftarrow get_byte$ ; {  $cur_gf = boc1$  }  $min_x \leftarrow get_byte; max_x \leftarrow get_byte; min_x \leftarrow max_x - min_x;$  $min_y \leftarrow get_byte; max_y \leftarrow get_byte; min_y \leftarrow max_y - min_y;$ end: if  $max_x - min_x > widest_row$  then  $abort(`Character_too_wide!`)$ 

This code is used in section 164.

**166.**  $\langle \text{Globals in the outer block 12} \rangle +\equiv char\_code, ext: integer; { the current character code and extension } min\_x, max\_x, min\_y, max\_y: integer; { character boundaries, in pixels } x, y: integer; { current painting position, in pixels } z: integer; { initial painting position in row, relative to min\_x }$ 

167. METAFONT coordinates (x, y) are converted to DVI coordinates by the following routine. Real values  $x_ratio$ ,  $y_ratio$ , and  $slant_ratio$  will have been calculated based on the gray font; scaled values  $delta_x$  and  $delta_y$  will have been computed so that, in the absence of slanting and offsets, the METAFONT coordinates  $(min_x, max_y + 1)$  will correspond to the DVI coordinates (0, 50 pt).

```
procedure convert(x, y : scaled);
```

```
begin x \leftarrow x + x_{-}offset; y \leftarrow y + y_{-}offset; dvi_y \leftarrow -round(y_ratio * y) + delta_y; dvi_x \leftarrow round(x_ratio * x + slant_ratio * y) + delta_x; end;
```

```
168. \langle Globals in the outer block 12 \rangle +\equiv

x_ratio, y_ratio, slant_ratio: real; { conversion factors }

<math>unsc_x_ratio, unsc_y_ratio, unsc_slant_ratio: real; { ditto, times unity }

fudge_factor: real; { unconversion factor }

delta_x, delta_y: scaled; { magic constants used by convert }

<math>dvi_x, dvi_y: scaled; { outputs of convert, in scaled points }

over_col: scaled; { overflow labels start here }

page_height, page_width: scaled; { size of the current page }
```

```
169. (Initialize global variables that depend on the font data 137) +≡
i ← char_info(gray_font)(1);
if ¬char_exists(i) then abort(`Missing_pixel_char!`);
unsc_x_ratio ← char_width(gray_font)(i); x_ratio ← unsc_x_ratio/unity;
unsc_y_ratio ← char_height(gray_font)(height_depth(i)); y_ratio ← unsc_y_ratio/unity;
unsc_slant_ratio ← slant(gray_font) * y_ratio; slant_ratio ← unsc_slant_ratio/unity;
if x_ratio * y_ratio = 0 then abort(`Vanishing_pixel_size!`);
fudge_factor ← (slant_ratio/x_ratio)/y_ratio;
```

```
170. (Get ready to convert METAFONT coordinates to DVI coordinates 170) \equiv
  if pre\_min\_x < min\_x * unity then offset\_x \leftarrow offset\_x + min\_x * unity - pre\_min\_x;
  if pre_max_y > max_y * unity then offset_y \leftarrow offset_y + max_y * unity - pre_max_y;
  if pre_max_x > max_x * unity then pre_max_x \leftarrow pre_max_x div unity
  else pre\_max\_x \leftarrow max\_x;
  if pre\_min\_y < min\_y * unity then pre\_min\_y \leftarrow pre\_min\_y div unity
  else pre\_min\_y \leftarrow min\_y;
  delta_y \leftarrow round(unsc_y ratio * (max_y + 1) - y_ratio * offset_y) + 3276800;
  delta_x \leftarrow round(x_ratio * offset_x - unsc_x_ratio * min_x);
  if slant_ratio \geq 0 then over_col \leftarrow round(unsc_x_ratio * pre_max_x + unsc_slant_ratio * max_y)
  else over\_col \leftarrow round(unsc\_x\_ratio * pre\_max\_x + unsc\_slant\_ratio * min\_y);
  over\_col \leftarrow over\_col + delta\_x + 10000000;
  page_height \leftarrow round(unsc_y-ratio * (max_y + 1 - pre_min_y)) + 3276800 - offset_y;
  if page_height > max_v then max_v \leftarrow page_height;
  page\_width \leftarrow over\_col - 10000000
This code is used in section 164.
```

171. The  $dvi_goto$  subroutine outputs bytes to the DVI file that will initiate typesetting at given DVI coordinates, assuming that the current position of the DVI reader is (0,0). This subroutine begins by outputting a *push* command; therefore, a *pop* command should be given later. That *pop* will restore the DVI position to (0,0).

```
procedure dvi_goto(x, y : scaled);
  begin dvi_out(push);
  if x \neq 0 then
    begin dvi_out(right_4); dvi_four(x);
    end;
  if y \neq 0 then
    begin dvi_out(down_4); dvi_four(y);
    end:
  end;
172.
        (Output the bop and the title line 172) \equiv
  dvi_out(bop); incr(total_pages); dvi_four(total_pages); dvi_four(char_code); dvi_four(ext);
  for k \leftarrow 3 to 9 do dvi_four(0);
  dvi_four(last_bop); last_bop \leftarrow dvi_offset + dvi_ptr - 45;
  dvi_goto(0, 655360); \{ \text{the top baseline is } 10 \text{ pt down} \}
  if use_logo then
    begin select_font(logo_font); hbox(small_logo, logo_font, true);
    end:
  select_font(title_font); hbox(time_stamp, title_font, true);
  hbox(page_header, title_font, true); dvi_scaled(total_pages * 65536.0);
  if (char_code \neq 0) \lor (ext \neq 0) then
    begin hbox(char_header, title_font, true); dvi_scaled(char_code * 65536.0);
    if ext \neq 0 then

begin typeset(k); dvi\_out(z_0); decr(p);

end;

end
```

This code is used in section 178.

**181.** Now we come to a more interesting part of the computation, where we go through the stored labels and try to fit them in the illustration for the current character, together with their associated dots.

It would simplify font-switching slightly if we were to typeset the labels first, but we find it desirable to typeset the dots first and then turn to the labels. This procedure makes it possible for us to allow the dots to overlap each other without allowing the labels to overlap. After the dots are in place, we typeset all prescribed labels, that is, labels with a *lab\_typ* of "1" ... "8"; these, too, are allowed to overlap the dots and each other.

```
(Output all labels for the current character 181 ) ≡
overflow_line ← 1;
if label_head ≠ null then
begin next[label_tail] ← null; select_font(gray_font); (Output all dots 187);
(Find nearest dots, to help in label positioning 191);
select_font(label_font); (Output all prescribed labels 189);
(Output all attachable labels 193);
(Output all overflow labels 200);
end
This code is used in section 164.
```

**182.**  $\langle$  Globals in the outer block  $12 \rangle +\equiv$ 

overflow\_line: integer; { the number of labels that didn't fit, plus 1 }

**183.** A label that appears above its dot is considered to occupy a rectangle of height  $h + \Delta$ , depth d, and width  $w + 2\Delta$ , where (h, w, d) are the height, width, and depth of the label computed by hbox, and  $\Delta$  is an additional amount of blank space that keeps labels from coming too close to each other. (GFtoDVI arbitrarily defines  $\Delta$  to be one half the width of a space in the label font.) This label is centered over its dot, with its baseline d + h' above the center of the dot; here  $h' = dot_height$  is the height of character 0 in the gray font.

Similarly, a label that appears below its dot is considered to occupy a rectangle of height h, depth  $d + \Delta$ , and width  $w + 2\Delta$ ; the baseline is h + h' below the center of the dot.

A label at the right of its dot is considered to occupy a rectangle of height  $h + \Delta$ , depth  $d + \Delta$ , and width  $w + \Delta$ . Its reference point can be found by starting at the center of the dot and moving right  $w' = dot_width$  (i.e., the width of character 0 in the gray font), then moving down by half the x-height of the label font. A label at the left of its dot is similar.

A dot is considered to occupy a rectangle of height 2h' and width 2w', centered on the dot.

When the label type is "1" or more, the labels are put into the doubly linked list unconditionally. Otherwise they are put into the list only if we can find a way to fit them in without overlapping any previously inserted rectangles.

 $\langle \text{Globals in the outer block } 12 \rangle + \equiv$ 

 $\begin{array}{ll} delta: \ scaled; & \{ \text{extra padding to keep labels from being too close } \\ half\_x\_height: \ scaled; & \{ \text{amount to drop baseline of label below the dot center } \\ thrice\_x\_height: \ scaled; & \{ \text{baseline separation for overflow labels } \\ dot\_width, \ dot\_height: \ scaled; & \{ w' \ \text{and } h' \ \text{in the discussion above } \} \end{array}$ 

184. (Initialize global variables that depend on the font data 137)  $+\equiv$ 

 $i \leftarrow char_info(gray_font)(0);$ 

if  $\neg char\_exists(i)$  then  $abort(`Missing\_dot\_char!`);$ 

 $dot\_width \leftarrow char\_width(gray\_font)(i); \ dot\_height \leftarrow char\_height(gray\_font)(height\_depth(i));$ 

 $delta \leftarrow space(label_font) \operatorname{div} 2; thrice_x_height \leftarrow 3 * x_height(label_font); half_x_height \leftarrow thrice_x_height \operatorname{div} 6;$ 

**185.** Here is a subroutine that computes the rectangle boundaries xl[p], xr[p], yt[p], yb[p], and the reference point coordinates xx[p], yy[p], for a label that is to be placed above a dot. The coordinates of the dot's center are assumed given in  $dvi_x$  and  $dvi_y$ ; the *hbox* subroutine is assumed to have already computed the height, width, and depth of the label box.

**procedure** *top\_coords*(*p* : *node\_pointer*);

**begin**  $xx[p] \leftarrow dvi\_x - (box\_width \operatorname{\mathbf{div}} 2); xl[p] \leftarrow xx[p] - delta; xr[p] \leftarrow xx[p] + box\_width + delta; yb[p] \leftarrow dvi\_y - dot\_height; yy[p] \leftarrow yb[p] - box\_depth; yt[p] \leftarrow yy[p] - box\_height - delta; end;$ 

186. The other three label positions are handled by similar routines.

**procedure**  $bot\_coords(p:node\_pointer);$  **begin**  $xx[p] \leftarrow dvi\_x - (box\_width \operatorname{\mathbf{div}} 2); xl[p] \leftarrow xx[p] - delta; xr[p] \leftarrow xx[p] + box\_width + delta;$  $<math>yt[p] \leftarrow dvi\_y + dot\_height; yy[p] \leftarrow yt[p] + box\_height; yb[p] \leftarrow yy[p] + box\_depth + delta;$  **end**; **procedure**  $right\_coords(p:node\_pointer);$  **begin**  $xl[p] \leftarrow dvi\_x + dot\_width; xx[p] \leftarrow xl[p]; xr[p] \leftarrow xx[p] + box\_width + delta;$  $<math>yy[p] \leftarrow dvi\_y + half\_x\_height; yb[p] \leftarrow yy[p] + box\_depth + delta; yt[p] \leftarrow yy[p] - box\_height - delta;$  **end**; **procedure**  $left\_coords(p:node\_pointer);$  **begin**  $xr[p] \leftarrow dvi\_x - dot\_width; xx[p] \leftarrow xr[p] - box\_width; xl[p] \leftarrow xx[p] - delta;$   $yy[p] \leftarrow dvi\_y + half\_x\_height; yb[p] \leftarrow yy[p] + box\_depth + delta; yt[p] \leftarrow xy[p] - delta;$  **end**; **procedure**  $left\_coords(p:node\_pointer);$  **begin**  $xr[p] \leftarrow dvi\_x - dot\_width; xx[p] \leftarrow xr[p] - box\_width; xl[p] \leftarrow xx[p] - delta;$   $yy[p] \leftarrow dvi\_y + half\_x\_height; yb[p] \leftarrow yy[p] + box\_depth + delta; yt[p] \leftarrow yy[p] - box\_height - delta;$  **ind**; **187.** (Output all dots 187)  $\equiv$   $p \leftarrow label\_head; first\_dot \leftarrow max\_node + 1;$ **while**  $n \neq nvll$  **do** 

```
p \leftarrow label\_head; \ first\_dot \leftarrow max\_node + 1;

while p \neq null do

begin convert(xx[p], yy[p]); \ xx[p] \leftarrow dvi\_x; \ yy[p] \leftarrow dvi\_y;

if lab\_typ[p] < "5" then \langle Enter a dot for label p in the rectangle list, and typeset the dot 188\rangle;

p \leftarrow next[p];

end
```

This code is used in section 181.

**188.** We plant links between dots and their labels by using (or abusing) the *xl* and *info* fields, which aren't needed for their normal purposes.

define  $dot_{for\_label} \equiv xl$ define  $label_{for\_dot} \equiv info$   $\langle$  Enter a dot for label p in the rectangle list, and typeset the dot  $188 \rangle \equiv$ begin  $q \leftarrow get\_avail$ ;  $dot\_for\_label[p] \leftarrow q$ ;  $label\_for\_dot[q] \leftarrow p$ ;  $xx[q] \leftarrow dvi\_x$ ;  $xl[q] \leftarrow dvi\_x - dot\_width$ ;  $xr[q] \leftarrow dvi\_x + dot\_width$ ;  $yy[q] \leftarrow dvi\_y$ ;  $yt[q] \leftarrow dvi\_y - dot\_height$ ;  $yb[q] \leftarrow dvi\_y + dot\_height$ ;  $node\_ins(q, 0)$ ;  $dvi\_goto(xx[q], yy[q])$ ;  $dvi\_out(0)$ ;  $dvi\_out(pop)$ ; end

This code is used in section 187.

189. Prescribed labels are now taken out of the singly linked list and inserted into the doubly linked list.

 $\begin{array}{l} \langle \text{Output all prescribed labels 189} \rangle \equiv \\ q \leftarrow end\_of\_list; \quad \{ label\_head = next[q] \} \\ \textbf{while } next[q] \neq null \ \textbf{do} \\ \textbf{begin } p \leftarrow next[q]; \\ \textbf{if } lab\_typ[p] > "0" \ \textbf{then} \\ \textbf{begin } next[q] \leftarrow next[p]; \\ \langle \text{Enter a prescribed label for node } p \ \textbf{into the rectangle list, and typeset it 190} \rangle; \\ \textbf{end} \\ \textbf{else } q \leftarrow next[q]; \\ \textbf{end} \end{array}$ 

This code is used in section 181.

**190.**  $\langle \text{Enter a prescribed label for node } p \text{ into the rectangle list, and typeset it } 190 \rangle \equiv$  **begin**  $hbox(info[p], label_font, false); {Compute the size of this label }$  $<math>dvi_x \leftarrow xx[p]; dvi_y \leftarrow yy[p];$  **if**  $lab_typ[p] < "5"$  **then**  $r \leftarrow dot_for_label[p]$  **else**  $r \leftarrow 0;$  **case**  $lab_typ[p]$  **of** "1", "5":  $top\_coords(p);$ "2", "6":  $left\_coords(p);$ "3", "7":  $right\_coords(p);$ "4", "8":  $bot\_coords(p);$  **end**; {no other cases are possible }  $node\_ins(p,r);$   $dvi\_goto(xx[p], yy[p]); hbox(info[p], label\_font, true); dvi\_out(pop);$  **end** This code is used in section 189.

191. GFtoDVI's algorithm for positioning the "floating" labels was devised by Arthur L. Samuel. It tries to place labels in a priority order, based on the position of the nearest dot to a given dot. If that dot, for example, lies in the first octant (i.e., east to northeast of the given dot), the given label will be put into the west slot unless that slot is already blocked; then the south slot will be tried, etc.

First we need to compute the octants. We also note if two or more dots are nearly coincident, since Samuel's algorithm modifies the priority order on that case. The information is temporarily recorded in the xr array.

**define**  $octant \equiv xr$  { octant code for nearest dot, plus 8 for coincident dots }

 $\langle \text{Find nearest dots, to help in label positioning 191} \rangle \equiv p \leftarrow label_head;$ while  $p \neq null$  do begin if  $lab\_typ[p] \leq "0"$  then  $\langle \text{Compute the octant code for floating label } p \ 192 \rangle;$   $p \leftarrow next[p];$ end;

This code is used in section 181.

**192.** There's a sneaky way to identify octant numbers, represented by the code shown here. (Remember that y coordinates increase downward in the DVI convention.)

define  $first\_octant = 0$ define  $second\_octant = 1$ define  $third\_octant = 2$ define  $fourth\_octant = 3$ define  $fifth\_octant = 7$ define  $sixth\_octant = 6$ define  $seventh\_octant = 5$ define  $eighth\_octant = 4$  $\langle Compute the octant code for floating label p 192 \rangle \equiv$ 

 $\begin{array}{l} \textbf{begin } r \leftarrow dot\_for\_label[p]; \ q \leftarrow nearest\_dot(r,10); \\ \textbf{if } twin \ \textbf{then } octant[p] \leftarrow 8 \ \textbf{else } octant[p] \leftarrow 0; \\ \textbf{if } q \neq null \ \textbf{then } \\ \textbf{begin } dx \leftarrow xx[q] - xx[r]; \ dy \leftarrow yy[q] - yy[r]; \\ \textbf{if } dy > 0 \ \textbf{then } octant[p] \leftarrow octant[p] + 4; \\ \textbf{if } dx < 0 \ \textbf{then } incr(octant[p]); \\ \textbf{if } dy > dx \ \textbf{then } incr(octant[p]); \\ \textbf{if } -dy > dx \ \textbf{then } incr(octant[p]); \\ \textbf{end; } \end{array}$ 

```
end
```

This code is used in section 191.

**193.** A procedure called *place\_label* will try to place the remaining labels in turn. If it fails, we "disconnect" the dot from this label so that an unlabeled dot will not appear as a reference in the overflow column.

```
 \begin{array}{l} \langle \text{Output all attachable labels } 193 \rangle \equiv \\ q \leftarrow end\_of\_list; \quad \{ \text{now } next[q] = label\_head \} \\ \text{while } next[q] \neq null \ \text{do} \\ \text{begin } p \leftarrow next[q]; \ r \leftarrow next[p]; \ s \leftarrow dot\_for\_label[p]; \\ \text{if } place\_label(p) \ \text{then } next[q] \leftarrow r \\ \text{else begin } label\_for\_dot[s] \leftarrow null; \quad \{ \text{disconnect the dot } \} \\ \text{ if } lab\_typ[p] = "/" \ \text{then } next[q] \leftarrow r \quad \{ \text{remove label from list } \} \\ \text{ else } q \leftarrow p; \quad \{ \text{ retain label in list for the overflow column } \} \\ \text{ end;} \\ \end{array}
```

This code is used in section 181.

**194.** Here is the *place\_label* routine, which uses the previously computed *octant* information as a heuristic. If the label can be placed, it is inserted into the rectangle list and typeset.

function place\_label(p: node\_pointer): boolean; label exit, found; var oct: 0.. 15; { octant code } dfl: node\_pointer; { saved value of dot\_for\_label[p] } begin hbox(info[p], label\_font, false); { Compute the size of this label } dvi\_x \leftarrow xx[p]; dvi\_y \leftarrow yy[p]; \langle Find non-overlapping coordinates, if possible, and goto found; otherwise set place\_label \leftarrow false and return 195 >; found: node\_ins(p, dfl); dvi\_goto(xx[p], yy[p]); hbox(info[p], label\_font, true); dvi\_out(pop); place\_label \leftarrow true;

exit: end;

**195.** (Find non-overlapping coordinates, if possible, and **goto** found; otherwise set  $place\_label \leftarrow false$  and **return**  $195 \rangle \equiv$ 

 $dfl \leftarrow dot\_for\_label[p]; oct \leftarrow octant[p]; \langle Try the first choice for label direction 196 \rangle;$ 

 $\langle$  Try the second choice for label direction 197 $\rangle$ ;

 $\langle \text{Try the third choice for label direction } 198 \rangle;$ 

 $\langle$  Try the fourth choice for label direction 199 $\rangle;$ 

 $xx[p] \leftarrow dvi_x; yy[p] \leftarrow dvi_y; dot_for_label[p] \leftarrow dfl; \{ no luck; restore the coordinates \}$  $place_label \leftarrow false; return$ 

This code is used in section 194.

**196.**  $\langle$  Try the first choice for label direction  $196 \rangle \equiv$ 

## $\mathbf{case} \ oct \ \mathbf{of}$

 $\begin{array}{l} \textit{first\_octant, fourth\_octant, fifth\_octant + 8, eighth\_octant + 8: bot\_coords(p);} \\ \textit{second\_octant, seventh\_octant, third\_octant + 8, sixth\_octant + 8: left\_coords(p);} \\ \textit{third\_octant, sixth\_octant, second\_octant + 8, seventh\_octant + 8: right\_coords(p);} \\ \textit{fifth\_octant, eighth\_octant, first\_octant + 8, fourth\_octant + 8: top\_coords(p);} \\ \textbf{end}; \end{array}$ 

if  $\neg overlap(p, dfl)$  then goto found

This code is used in section 195.

**198.** (Try the third choice for label direction 198)  $\equiv$ 

## $\mathbf{case} \ oct \ \mathbf{of}$

 $first\_octant, fourth\_octant, sixth\_octant + 8, seventh\_octant + 8: top\_coords(p);$  $second\_octant, seventh\_octant, fourth\_octant + 8, fifth\_octant + 8: right\_coords(p);$  $third\_octant, sixth\_octant, first\_octant + 8, eighth\_octant + 8: left\_coords(p);$  $fifth\_octant, eighth\_octant, second\_octant + 8, third\_octant + 8: bot\_coords(p);$ end;

if  $\neg overlap(p, dfl)$  then goto found

This code is used in section 195.

**199.**  $\langle$  Try the fourth choice for label direction 199 $\rangle \equiv$ 

## $\mathbf{case} \ oct \ \mathbf{of}$

 $\begin{array}{l} \textit{first\_octant, eighth\_octant, first\_octant + 8, eighth\_octant + 8: right\_coords(p);} \\ \textit{second\_octant, third\_octant, second\_octant + 8, third\_octant + 8: top\_coords(p);} \\ \textit{fourth\_octant, fifth\_octant, fourth\_octant + 8, fifth\_octant + 8: left\_coords(p);} \\ \textit{sixth\_octant, seventh\_octant, sixth\_octant + 8, seventh\_octant + 8: bot\_coords(p);} \\ \textbf{end}; \end{array}$ 

if  $\neg overlap(p, dfl)$  then goto found

This code is used in section 195.

```
200. \langle \text{Output all overflow labels 200} \rangle \equiv \langle \text{Remove all rectangles from list, except for dots that have labels 201}; 
 <math>p \leftarrow label\_head;

while p \neq null do

begin \langle \text{Typeset an overflow label for } p | 202 \rangle;

p \leftarrow next[p];

end
```

This code is used in section 181.

**201.** When we remove a dot that couldn't be labeled, we set its *next* field to the preceding node that survives, so that we can use the *nearest\_dot* routine later. (This is a bit of a kludge.)

 $\langle$  Remove all rectangles from list, except for dots that have labels 201 $\rangle \equiv$ 

 $\begin{array}{l} p \leftarrow next[0];\\ \textbf{while } p \neq end\_of\_list \ \textbf{do}\\ \textbf{begin } q \leftarrow next[p];\\ \textbf{if } (p < first\_dot) \lor (label\_for\_dot[p] = null) \ \textbf{then}\\ \textbf{begin } r \leftarrow prev[p]; \ next[r] \leftarrow q; \ prev[q] \leftarrow r; \ next[p] \leftarrow r;\\ \textbf{end};\\ p \leftarrow q;\\ \textbf{end} \end{array}$ 

This code is used in section 200.

**202.** Now we have to insert *p* into the list temporarily, because of the way *nearest\_dot* works.

 $\begin{array}{l} \langle \text{Typeset an overflow label for } p \ 202 \rangle \equiv \\ \textbf{begin } r \leftarrow next[dot_for\_label[p]]; \ s \leftarrow next[r]; \ t \leftarrow next[p]; \ next[p] \leftarrow s; \ prev[s] \leftarrow p; \ next[r] \leftarrow p; \\ prev[p] \leftarrow r; \\ q \leftarrow nearest\_dot(p,0); \\ next[r] \leftarrow s; \ prev[s] \leftarrow r; \ next[p] \leftarrow t; \quad \{\text{remove } p \ \text{again} \} \\ incr(overflow\_line); \ dvi\_goto(over\_col, overflow\_line * thrice\_x\_height + 655360); \\ hbox(info[p], label\_font, true); \\ if \ q \neq null \ \textbf{then} \\ \quad \textbf{begin } hbox(equals\_sign, label\_font, true); \ hbox(info[label\_for\_dot[q]], label\_font, true); \\ hbox(plus\_sign, label\_font, true); \ dvi\_scaled((xx[p] - xx[q])/x\_ratio + (yy[p] - yy[q]) * fudge\_factor); \\ dvi\_out(","); \ dvi\_scaled((yy[q] - yy[p])/y\_ratio); \ dvi\_out(")"); \\ \mathbf{end}; \\ dvi\_out(pop); \\ \mathbf{end} \end{array}$ 

This code is used in section 200.

**203.** (Adjust the maximum page width 203) =

if  $overflow_line > 1$  then  $page_width \leftarrow over_col + 10000000;$ 

{ overflow labels are estimated to occupy  $10^7 \, \mathrm{sp}$  }

if  $page_width > max_h$  then  $max_h \leftarrow page_width$ 

This code is used in section 164.

204. Doing the pixels. The most interesting part of GFtoDVI is the way it makes use of a gray font to typeset the pixels of a character. In fact, the author must admit having great fun devising the algorithms below. Perhaps the reader will also enjoy reading them.

The basic idea will be to use an array of 12-bit integers to represent the next twelve rows that need to be typeset. The binary expansions of these integers, reading from least significant bit to most significant bit, will represent pixels from top to bottom.

**205.** We have already used such a binary representation in the tables c[1 ... 120] and d[1 ... 120] of bit patterns and lengths that are potentially present in a gray font; we shall now use those tables to compute an auxiliary array b[0 ... 4095]. Given a 12-bit number v, the gray-font character appropriate to v's binary pattern will be b[v]. If no character should be typeset for this pattern in the current row, b[v] will be 0.

The array b can have many different configurations, depending on how many characters are actually present in the gray font. But it's not difficult to compute b by going through the existing characters in increasing order and marking all patterns x to which they apply.

 $\langle$  Initialize global variables that depend on the font data  $137 \rangle + \equiv$ 

```
for k \leftarrow 0 to 4095 do b[k] \leftarrow 0;

for k \leftarrow font\_bc[gray\_font] to font\_ec[gray\_font] do

if k \ge 1 then

if k \le 120 then

if char\_exists(char\_info(gray\_font)(k)) then

begin v \leftarrow c[k];

repeat b[v] \leftarrow k; v \leftarrow v + d[k];

until v > 4095;

end;
```

**206.** We also compute an auxiliary array rho[0..4095] such that  $rho[v] = 2^j$  when v is an odd multiple of  $2^j$ ; we also set  $rho[0] = 2^{12}$ .

 $\langle$  Initialize global variables that depend on the font data  $137 \rangle + \equiv$ 

for  $j \leftarrow 0$  to 11 do begin  $k \leftarrow two\_to\_the[j]; v \leftarrow k;$ repeat  $rho[v] \leftarrow k; v \leftarrow v + k + k;$ until v > 4095;end;  $rho[0] \leftarrow 4096;$ 

**207.** (Globals in the outer block 12)  $+\equiv$ b: **array** [0..4095] **of** 0..120; {largest existing character for a given pattern } *rho*: **array** [0..4095] **of** 1..4096; {the "ruler function" } **208.** But how will we use these tables? Let's imagine that the DVI file already contains instructions that have selected the gray font and moved to the proper horizontal coordinate for the row that we wish to process next. Let's suppose that 12-bit patterns have been set up in array a, and that the global variables starting\_col and finishing\_col are known such that a[j] is zero unless starting\_col  $\leq j \leq finishing_col$ . Here's what we can do, assuming that appropriate local variables and labels have been declared:

```
\langle Typeset the pixels of the current row 208 \rangle \equiv
```

$$\begin{split} j \leftarrow starting\_col; \\ \textbf{loop begin while } (j \leq finishing\_col) \land (b[a[j]] = 0) \textbf{ do } incr(j); \\ \textbf{if } j > finishing\_col \textbf{ then goto } done; \\ dvi\_out(push); \langle \text{Move to column } j \text{ in the DVI output } 209 \rangle; \\ \textbf{repeat } v \leftarrow b[a[j]]; a[j] \leftarrow a[j] - c[v]; k \leftarrow j; incr(j); \\ \textbf{while } b[a[j]] = v \textbf{ do} \\ \textbf{begin } a[j] \leftarrow a[j] - c[v]; incr(j); \\ \textbf{end}; \\ k \leftarrow j - k; \langle \text{Output the equivalent of } k \text{ copies of character } v \text{ 210} \rangle; \\ \textbf{until } b[a[j]] = 0; \\ dvi\_out(pop); \\ \textbf{end}; \\ \end{split}$$

done:

This code is used in section 218.

```
209. \langle Move to column j in the DVI output 209 \rangle \equiv dvi_out(right_4); dvi_four(round(unsc_x_ratio * j + unsc_slant_ratio * y) + delta_x)
This code is used in section 208.
```

210. The doubling-up property of gray font character lists is utilized here.

```
\langle \text{Output the equivalent of } k \text{ copies of character } v \text{ 210} \rangle \equiv reswitch: \text{ if } k = 1 \text{ then } typeset(v)

else begin i \leftarrow char\_info(gray\_font)(v);

if char\_tag(i) = list\_tag \text{ then } \{v \text{ has a successor}\}

begin if odd(k) then typeset(v);

k \leftarrow k \text{ div } 2; v \leftarrow qo(rem\_byte(i)); \text{ goto } reswitch;

end

else repeat typeset(v); \ decr(k);

until k = 0;

end
```

This code is used in section 208.

**211.**  $\langle \text{Globals in the outer block } 12 \rangle +\equiv$ a: **array**  $[0 \dots widest\_row]$  of  $0 \dots 4095$ ; { bit patterns for twelve rows }

**212.** In order to use the approach above, we need to be able to initialize array a, and we need to be able to keep it up to date as new rows scroll by. A moment's thought about the problem reveals that we will either have to read an entire character from the GF file into memory, or we'll need to adopt a coroutine-like approach: A single *skip* command in the GF file might need to be processed in pieces, since it might generate more rows of zeroes than we are ready to absorb all at once into a.

The coroutine method actually turns out to be quite simple, so we shall introduce a global variable *blank\_rows*, which tells how many rows of blanks should be generated before we read the **GF** instructions for another row.

 $\begin{array}{l} \langle \mbox{ Globals in the outer block } 12 \,\rangle \ + \equiv \\ blank\_rows: \ integer; \quad \mbox{ from a previous } GF \ command \ \end{array}$ 

**213.** Initialization and updating of a can now be handled as follows, if we introduce another variable l that is set initially to 1:

 $\langle \text{Add more rows to } a, \text{ until 12-bit entries are obtained 213} \rangle \equiv$ **repeat**  $\langle \text{Put the bits for the next row, times } l, \text{ into } a \text{ 214} \rangle;$  $l \leftarrow l + l; \ decr(y);$ **until** l = 4096;This code is used in section 218.

214. As before, *cur\_gf* will contain the first GF command that has not yet been interpreted.

```
(Put the bits for the next row, times l, into a 214) \equiv
  if blank_rows > 0 then decr(blank_rows)
  else if cur_{gf} \neq eoc then
       begin x \leftarrow z;
       if starting_col > x then starting_col \leftarrow x;
       \langle \text{Read and process GF commands until coming to the end of this row 215} \rangle;
       end;
This code is used in section 213.
215.
        define do_skip \equiv z \leftarrow 0; paint_black \leftarrow false
  define end_with(\#) \equiv
             begin #; cur_gf \leftarrow get_byte; goto done1; end
  define five_cases(\#) \equiv \#, \# + 1, \# + 2, \# + 3, \# + 4
  define eight\_cases(\#) \equiv \#, \# + 1, \# + 2, \# + 3, \# + 4, \# + 5, \# + 6, \# + 7
  define thirty_two_cases(\#) \equiv eight_cases(\#), eight_cases(\#+8), eight_cases(\#+16), eight_cases(\#+24)
  define sixty_four_cases(\#) \equiv thirty_two_cases(\#), thirty_two_cases(\# + 32)
(Read and process GF commands until coming to the end of this row 215) \equiv
  loop begin continue: case cur_qf of
     sixty_four_cases(0): k \leftarrow cur_qf;
     paint1: k \leftarrow qet_byte;
     paint2: k \leftarrow qet\_two\_bytes;
     paint3: k \leftarrow qet\_three\_bytes;

       end;
     othercases bad_gf(`Improper_opcode`)
     endcases;
     (Paint k bits and read another command 216);
     end;
done1:
This code is used in section 214.
```

**216.** (Paint k bits and read another command 216)  $\equiv$  **if**  $x + k > finishing\_col$  **then** finishing\\_col  $\leftarrow x + k$ ; **if** paint\_black **then for**  $j \leftarrow x$  **to** x + k - 1 **do**  $a[j] \leftarrow a[j] + l$ ; paint\_black  $\leftarrow \neg paint\_black$ ;  $x \leftarrow x + k$ ;  $cur\_gf \leftarrow get\_byte$ This code is used in section 215.

**217.** When the current row has been typeset, all entries of a will be even; we want to divide them by 2 and incorporate a new row with  $l = 2^{11}$ . However, if they are all multiples of 4, we actually want to divide by 4 and incorporate two new rows, with  $l = 2^{10}$  and  $l = 2^{11}$ . In general, we want to divide by the maximum possible power of 2 and add the corresponding number of new rows; that's where the *rho* array comes in handy:

 $\langle \text{Advance to the next row that needs to be typeset; or$ **return** $, if we're all done 217 <math>\rangle \equiv l \leftarrow rho[a[starting\_col]];$ 

for  $j \leftarrow starting\_col + 1$  to finishing\\_col do if l > rho[a[j]] then  $l \leftarrow rho[a[j]]$ ; if l = 4096 then if  $cur\_gf = eoc$  then return else begin  $y \leftarrow y - blank\_rows$ ;  $blank\_rows \leftarrow 0$ ;  $l \leftarrow 1$ ;  $starting\_col \leftarrow z$ ; finishing\\_col  $\leftarrow z$ ; end else begin while  $a[starting\_col] = 0$  do  $incr(starting\_col)$ ; while  $a[finishing\_col] = 0$  do  $decr(finishing\_col)$ ; for  $j \leftarrow starting\_col = 0$  do  $a[j] \leftarrow a[j]$  div l;  $l \leftarrow 4096$  div l; end

This code is used in section 218.

**218.** We now have constructed the major components of the necessary routine; it simply remains to glue them all together in the proper framework.

procedure *do\_pixels*; **label** done, done1, reswitch, continue, exit; **var** paint\_black: boolean; { the paint switch } starting\_col, finishing\_col: 0... widest\_row; { currently nonzero area } *j*: 0...*widest\_row*; { for traversing that area } *l: integer*; { power of two used to manipulate bit patterns } *i*: *four\_quarters*; { character information word } v: *eight\_bits*; { character corresponding to a pixel pattern } **begin** select\_font(gray\_font); delta\_x \leftarrow delta\_x + round(unsc\_x\_ratio \* min\_x); for  $j \leftarrow 0$  to  $max_x - min_x$  do  $a[j] \leftarrow 0$ ;  $l \leftarrow 1; z \leftarrow 0; starting\_col \leftarrow 0; finishing\_col \leftarrow 0; y \leftarrow max\_y + 12; paint\_black \leftarrow false;$  $blank_rows \leftarrow 0; \ cur_qf \leftarrow get_byte;$ **loop begin** (Add more rows to a, until 12-bit entries are obtained 213);  $dvi_goto(0, delta_y - round(unsc_y_ratio * y)); \langle Typeset the pixels of the current row 208 \rangle;$  $dvi_out(pop)$ ; (Advance to the next row that needs to be typeset; or **return**, if we're all done 217); end; exit: end;

**219.** The main program. Now we are ready to put it all together. This is where GFtoDVI starts, and where it ends.

**begin** *initialize*; { get all variables initialized }  $\langle \text{Initialize the strings 77} \rangle$ ;  $start\_gf$ ; { open the input and output files }  $\langle \text{Process the preamble 221} \rangle$ ;  $cur\_gf \leftarrow get\_byte$ ;  $init\_str\_ptr \leftarrow str\_ptr$ ; **loop begin**  $\langle \text{Initialize variables for the next character 144} \rangle$ ; **while**  $(cur\_gf \ge xxx1) \land (cur\_gf \le no\_op)$  **do**  $\langle \text{Process a no-op command 154} \rangle$ ; **if**  $cur\_gf = post$  **then**  $\langle \text{Finish the DVI file and goto final\_end 115} \rangle$ ; **if**  $cur\_gf \ne boc$  **then if**  $cur\_gf \ne boc1$  **then**  $abort(\text{`Missing\_boc!`})$ ;  $\langle \text{Process a character 164} \rangle$ ;  $cur\_gf \leftarrow get\_byte$ ;  $str\_ptr \leftarrow init\_str\_ptr$ ;  $pool\_ptr \leftarrow str\_start[str\_ptr]$ ; **end**; final\\_end: **end**.

220. The main program needs a few global variables in order to do its work.

 $\langle \text{Globals in the outer block } 12 \rangle +\equiv k, m, p, q, r, s, t, dx, dy: integer; { general purpose registers } time_stamp: str_number; { the date and time when the input file was made } use_logo: boolean; { should METAFONT's logo be put on the title line? }$ 

221. METAFONT sets the opening string to 32 bytes that give date and time as follows:

```
´⊔METAFONT⊔output⊔yyyy.mm.dd:tttt´
```

We copy this to the DVI file, but remove the 'METAFONT' part so that it can be replaced by its proper logo.  $\langle Process the preamble 221 \rangle \equiv$ 

```
if get_byte \neq pre then bad_gf(\text{No}preamble);
  if get\_byte \neq gf\_id\_byte then bad\_gf(`Wrong_{\sqcup}ID`);
  k \leftarrow get_byte; \{k \text{ is the length of the initial string to be copied}\}
  for m \leftarrow 1 to k do append_char(get_byte);
  dvi_out(pre); dvi_out(dvi_id_byte); { output the preamble }
  dvi_four(25400000); dvi_four(473628672); \{ conversion ratio for sp \}
  dvi_four(1000); \{ magnification factor \}
  dvi_out(k); use_logo \leftarrow false; s \leftarrow str_start[str_ptr];
  for m \leftarrow 1 to k do dvi_out(str_pool[s+m-1]);
  if str_pool[s] = "_{\downarrow\downarrow}" then
    if str_pool[s+1] = "M" then
       if str_pool[s+2] = "E" then
         if str_pool[s+3] = "T" then
            if str_pool[s+4] = "A" then
               if str_pool[s+5] = "F" then
                 if str_pool[s+6] = "0" then
                    if str_pool[s+7] = "N" then
                      if str_pool[s+8] = "T" then
                         begin incr(str_ptr); str_start[str_ptr] \leftarrow s + 9; use_logo \leftarrow true;
                         end; { we will substitute 'METAFONT' for METAFONT }
  time\_stamp \leftarrow make\_string
This code is used in section 219.
```

222. System-dependent changes. This section should be replaced, if necessary, by changes to the program that are necessary to make GFtoDVI work at a particular installation. It is usually best to design your change file so that all changes to previous sections preserve the section numbering; then everybody's version will be consistent with the printed program. More extensive changes, which introduce new sections, can be inserted here; then only the index itself will get a new section number.

**223.** Index. Here is a list of the section numbers where each identifier is used. Cross references to error messages and a few other tidbits of information also appear.

- $\langle \text{Read font parameters } 68 \rangle$  Used in section 59.
- $\langle \text{Read ligature/kern program 66} \rangle$  Used in section 59.
- $\langle \text{Read the next } k \text{ characters of the GF file; change } c \text{ and } \textbf{goto } done \text{ if a keyword is recognized } 82 \rangle$  Used in section 81.
- $\langle \text{Read the TFM header 62} \rangle$  Used in section 59.
- $\langle \text{Read the TFM size fields } 60 \rangle$  Used in section 59.
- $\langle$  Remove all rectangles from list, except for dots that have labels 201 $\rangle$  Used in section 200.
- (Replace z by z' and compute  $\alpha, \beta$  65) Used in section 64.
- $\langle$  Scan the file name in the buffer 95  $\rangle$  Used in section 94.
- $\langle$  Search buffer for valid keyword; if successful, **goto** found 100  $\rangle$  Used in section 99.
- (Search for the nearest dot in nodes following  $p_{151}$ ) Used in section 150.
- $\langle$  Search for the nearest dot in nodes preceding  $p_{152} \rangle$  Used in section 150.
- (Set initial values 13, 14, 15, 54, 97, 103, 106, 118, 126, 142) Used in section 3.
- $\langle \text{Store a label } 163 \rangle$  Used in section 154.
- $\langle$  Store a rule 159 $\rangle$  Used in section 154.
- $\langle$  Store a title 162  $\rangle$  Used in section 154.
- $\langle$  Try the first choice for label direction 196 $\rangle$  Used in section 195.
- $\langle$  Try the fourth choice for label direction 199 $\rangle$  Used in section 195.
- $\langle$  Try the second choice for label direction 197 $\rangle$  Used in section 195.
- $\langle$  Try the third choice for label direction 198 $\rangle$  Used in section 195.
- $\langle Try to output a diagonal rule 178 \rangle$  Used in section 173.
- $\langle Types in the outer block 9, 10, 11, 45, 52, 70, 79, 104, 139 \rangle$  Used in section 3.
- (Typeset a space in font f and advance k | 119) Used in section 116.
- $\langle \text{Typeset an overflow label for } p | 202 \rangle$  Used in section 200.
- $\langle Typeset character cur_l, if it exists in the font; also append an optional kern 121 \rangle$  Used in section 116.
- $\langle Typeset the pixels of the current row 208 \rangle$  Used in section 218.
- $\langle \text{Update the font name or area } 101 \rangle$  Used in section 99.
- $\langle$  Use size fields to allocate font information 61  $\rangle$  Used in section 59.
- (Vertically typeset p copies of character k + 1 180) Used in section 178.
- (Vertically typeset q copies of character k 179) Used in section 178.
