The POOLtype processor

(Version 3, September 1989)

	Section	Page
Introduction	1	102
The character set	4	103
String handling	12	104
System-dependent changes	21	105
Index	25	106

Editor's Note: The present variant of this C/WEB source file has been modified for use in the $T_{E}X$ Live system.

The following sections were changed by the change file: 1, 2, 6, 10, 15, 18, 19, 20, 21, 22, 23, 24, 25.

The preparation of this report was supported in part by the National Science Foundation under grants IST-8201926 and MCS-8300984, and by the System Development Foundation. 'T_EX' is a trademark of the American Mathematical Society.

1* Introduction. The POOLtype utility program converts string pool files output by TANGLE into a slightly more symbolic format that may be useful when TANGLEd programs are being debugged.

It's a pretty trivial routine, but people may want to try transporting this program before they get up enough courage to tackle T_EX itself. The first 256 strings are treated as T_EX treats them, using routines copied from T_EX82 .

define $my_name \equiv \text{`pooltype'}$

2* POOLtype is written entirely in standard Pascal, except that it has to do some slightly system-dependent character code conversion on input and output. The input is read from *pool_file*, and the output is written on *output*. If the input is erroneous, the *output* file will describe the error.

program POOLtype(pool_file, output);
type \ Types in the outer block 5 \
var \ Globals in the outer block 7 \
 \ Define parse_arguments 21* \
 procedure initialize; { this procedure gets things started properly }
 var \ Local variables for initialization 6* \
 begin kpse_set_program_name(argv[0], my_name); parse_arguments;
 \ Set initial values of key variables 8 \
 end;

6^{*} The original Pascal compiler was designed in the late 60s, when six-bit character sets were common, so it did not make provision for lowercase letters. Nowadays, of course, we need to deal with both capital and small letters in a convenient way, especially in a program for typesetting; so the present specification of T_{EX} has been written under the assumption that the Pascal compiler and run-time system permit the use of text files with more than 64 distinguishable characters. More precisely, we assume that the character set contains at least the letters and symbols associated with ASCII codes '40 through '176; all of these characters are now available on most computer terminals.

Since we are dealing with more characters than were present in the first Pascal compilers, we have to decide what to call the associated data type. Some Pascals use the original name *char* for the characters in text files, even though there now are more than 64 such characters, while other Pascals consider *char* to be a 64-element subrange of a larger data type that has some other name.

In order to accommodate this difference, we shall use the name $text_char$ to stand for the data type of the characters that are converted to and from $ASCII_code$ when they are input and output. We shall also assume that $text_char$ consists of the elements $chr(first_text_char)$ through $chr(last_text_char)$, inclusive. The following definitions should be adjusted if necessary.

define $text_char \equiv ASCII_code$ { the data type of characters in text files } **define** $first_text_char = 0$ { ordinal number of the smallest element of $text_char$ } **define** $last_text_char = 255$ { ordinal number of the largest element of $text_char$ }

 \langle Local variables for initialization $6^* \rangle \equiv$

i: integer;

This code is used in section 2^* .

10* The ASCII code is "standard" only to a certain extent, since many computer installations have found it advantageous to have ready access to more than 94 printing characters. Appendix C of The T_EXbook gives a complete specification of the intended correspondence between characters and T_FX 's internal representation.

If TEX is being used on a garden-variety Pascal for which only standard ASCII codes will appear in the input and output files, it doesn't really matter what codes are specified in xchr[0 ... 37], but the safest policy is to blank everything out by using the code shown below.

However, other settings of *xchr* will make T_EX more friendly on computers that have an extended character set, so that users can type things like ' \neq ' instead of '\ne'. People with extended character sets can assign codes arbitrarily, giving an *xchr* equivalent to whatever characters the users of T_EX are allowed to have in their input files. It is best to make the codes correspond to the intended interpretations as shown in Appendix C whenever possible; but this is not necessary. For example, in countries with an alphabet of more than 26 letters, it is usually best to map the additional letters into codes less than '40. To get the most "permissive" character set, change ' \Box ' on the right of these assignment statements to *chr*(*i*).

 $\langle \text{Set initial values of key variables } 8 \rangle + \equiv$ for $i \leftarrow 0$ to '37 do $xchr[i] \leftarrow chr(i);$

for $i \leftarrow '177$ to '377 do $xchr[i] \leftarrow chr(i)$;

15.* This is the main program, where POOLtype starts and ends.

```
define abort(#) \equiv
begin write_ln(stderr, #); uexit(1);
end
```

begin *initialize*;

```
\langle Make the first 256 strings 16 \rangle;

s \leftarrow 256;

\langle Read the other strings from the POOL file, or give an error message and abort 19*<math>\rangle;

write_ln(`(`, count : 1, `\_characters\_in\_all.)`); uexit(0);

end.
```

18* When the WEB system program called TANGLE processes a source file, it outputs a Pascal program and also a string pool file. The present program reads the latter file, where each string appears as a two-digit decimal length followed by the string itself, and the information is output with its associated index number. The strings are surrounded by double-quote marks; double-quotes in the string itself are repeated.

```
\langle \text{Globals in the outer block } 7 \rangle +\equiv pool_file: packed file of text_char; { the string-pool file output by TANGLE } pool_name: const_c_string; xsum: boolean; { has the check sum been found? }
```

```
19* (Read the other strings from the POOL file, or give an error message and abort 19^*) \equiv
  xsum \leftarrow false;
  if eof(pool_file) then abort(`!_{u}I_{u}can``t_{u}read_{u}the_POOL_file.`);
  repeat (Read one string, but abort if there are problems 20^*);
  until xsum;
  if \neg eof(pool_file) then abort(`!_There``s_junk_after_the_check_sum`)
This code is used in section 15^*.
20*
     \langle Read one string, but abort if there are problems 20^* \rangle \equiv
  if eof(pool_file) then abort(`!_POOL_file_contained_no_check_sum`);
  read(pool_file, m); read(pool_file, n); \{ read two digits of string length \}
  if m \neq \texttt{`*` then}
     begin if (xord[m] < "0") \lor (xord[m] > "9") \lor (xord[n] < "0") \lor (xord[n] > "9") then
       abort(`!_POOL_line_doesn``t_begin_with_two_digits`);
     l \leftarrow xord[m] * 10 + xord[n] - "0" * 11; \{ \text{compute the length} \}
     write (s:3, ::\_"); count \leftarrow count + l;
     for k \leftarrow 1 to l do
       begin if eoln(pool_file) then
          begin write_ln(`"`); abort(`!_That_POOL_line_was_too_short`);
         end:
       read(pool_file, m); write(xchr[xord[m]]);
       if xord[m] = """" then write(xchr[""""]);
       end;
     write_ln(""); incr(s);
     end
  else xsum \leftarrow true;
  read_ln(pool_file)
This code is used in section 19^*.
```

21* System-dependent changes. Parse a Unix-style command line.

define $argument_{is}(\#) \equiv (strcmp(long_options[option_index].name, \#) = 0)$ $\langle \text{Define parse_arguments } 21^* \rangle \equiv$ procedure *parse_arguments*; **const** $n_{-}options = 2$; { Pascal won't count array lengths for us. } **var** $long_options$: **array** $[0 ... n_options]$ **of** $getopt_struct$; getopt_return_val: integer; option_index: c_int_type; current_option: 0...n_options; **begin** (Define the option table 22^*); **repeat** getopt_return_val \leftarrow getopt_long_only(argc, argv, \checkmark , long_options, address_of(option_index)); if $getopt_return_val = -1$ then **begin** *do_nothing*; end else if getopt_return_val = `?` then **begin** usage(my_name); end else if *argument_is*(`help`) then **begin** *usage_help*(*POOLTYPE_HELP*, **nil**); end else if argument_is(`version`) then begin print_version_and_exit('This_is_POOLtype, Version_3.0', nil, 'D.E._Knuth', nil); end; { Else it was just a flag; *getopt* has already done the assignment. } until $qetopt_return_val = -1$; {Now optind is the index of first non-option on the command line.} if $(optind + 1 \neq argc)$ then **begin** write_ln(stderr, my_name, `:_Need_exactly_one_file_argument.`); usage(my_name); end: $pool_name \leftarrow extend_filename(cmdline(optind), `pool`);$ { Try opening the file here, to avoid printing the first 256 strings if they give a bad filename. } resetbin(pool_file, pool_name); end: This code is used in section 2^* .

22* Here are the options we allow. The first is one of the standard GNU options.

 $\langle \text{Define the option table } 22^* \rangle \equiv$

 $current_option \leftarrow 0; \ long_options[current_option].name \leftarrow `help`; \ long_options[current_option].has_arg \leftarrow 0; \ long_options[current_option].flag \leftarrow 0; \ long_options[current_option].val \leftarrow 0; \ incr(current_option); \ long_options[current_option].val \leftarrow 0; \ incr(current_option].val \leftarrow 0; \ incr(current_option); \ long_options[current_option].val \leftarrow 0; \ incr(current_option].val _option].val _option].val _option].val _option].val _option].val _$

See also sections 23^* and 24^* .

This code is used in section 21^* .

23* Another of the standard options.

 $\langle \text{Define the option table } 22^* \rangle +\equiv long_options[current_option].has_arg \leftarrow 0; long_options[current_option].flag \leftarrow 0; long_options[current_option].val \leftarrow 0; incr(current_option); long_options[current_option].val \leftarrow 0; incr(current_option].val \leftarrow 0; incr(current_option].val$

24^{*} An element with all zeros always ends the list.

```
\langle \text{Define the option table } 22^* \rangle +\equiv long_options[current_option].has_arg \leftarrow 0; long_options[current_option].has_arg \leftarrow 0; long_options[current_option].has_arg \leftarrow 0; long_options[current_option].val \leftarrow 0;
```

25.* Index. Indications of system dependencies appear here together with the section numbers where each identifier is used.
